Dr. Alexander Harkin.—We regret we have not by us a copy of the number of the publication mentioned.

SWALLOWING ARTIFICIAL TEETH.

To the Editors of THE LANCET.

SIRS,—I notice in recent issues of THE LANCET several interesting cases of the swallowing of coins, &c. Possibly the following case may be of similar interest to some of your readers.

On Friday last, about 8 A.M., I was called to see Mrs. B——, the messenger stating that she had swallowed her artificial teeth. On my arrival she said she was in the habit of sleeping with the teeth in the mouth, and that they comprised the four upper incisors, with a composition-plate fitting half the upper palate. On awaking, she found the teeth in her throat, and was obliged to swallow them. She complained of pain in the epigastrium and between the shoulders. I passed the horsehair probang down the œsophagus into the stomach, and gently moved it about in the stomach, but was unsuccessful in extracting the teeth. I repeated the operation three times unsuccessfully. I then administered an emetic consisting of one scruple of ipecacuanha powder and ten grains of sulphate of zinc in a cupful of warm tea, and directed the patient to eat a few figs, which she did. Having to leave to attend a labour case in an adjoining street, I called about an hour afterwards, and found that she had vomited the set embedded in the figs. During the after-part of the day she complained of the former pain between the shoulders and in the epigastrium, and was unable to lie down. Relief was obtained by ten-drop doses of tincture of opium and hot poultices applied back and front. On calling the next day I found her free from all pain, and to all appearance perfectly well—a happy issue out of her trouble.

I am, Sirs, yours truly,

GEO. W. EGLINTON, L.R.C.P. Ed., &c.

Dalton-in-Furness, Oct. 24th, 1887.

"LEICESTER PROTECTED BY VACCINATION."

Mr. Biggs.—We adhere to our approval of inquiry "by competent and unprejudiced persons." But we did not contemplate the nomination of so many Leicester officials, who, according to our correspondent, believe in vaccination, but certainly have taken up a strongly antagonistic position to the Vaccination Acts. The constitution of such a committee would have to be gravely discussed, and the time for its appointment. As to the points in dispute between Mr. Biggs and ourselves there can be no doubt: That those exposed to small-pox patients in Leicester are protected by vaccination and revaccination, one nurse excepted, in whom revaccination at another small-pox hospital did "not take," and she, almost of course, incurred small pox, and so became protected; that Mr. Biggs in his account of the immunity of Leicester entirely ignored this protective influence, which, according to the overwhelming opinion of the medical profession and of all civilised nations, constitutes the chief security of Leicester, without which all the excellent police arrangements would not avail, as they will not avail for any Leicester man, woman, or child, when they come to be exposed to small-pox either out of Leicester or when it may come into Leicester "like a flood," and not in driblets, as now.

E. H. should apply to the Secretary of the St. John Ambulance Association, St. John's-gate, Clerkenwell.

G. M. O.—At this distance it is impossible for us to discuss the details of a matter which has been the subject of judicial inquiry.

MORE "ROUGH-AND-READY MEDICAMENTS."

To the Editors of THE LANCET.

SIRS,—With reference to a letter of mine that appeared under this heading some time since in these pages, will you kindly allow me to give a few other illustrations in point, and to ask your readers for any or such others of like import as may have come under their notice.

1. Burnet is responsible for the first, and it occurs in his Life (p. 211) of that pious and kindly Anglican bishop, Dr. Bedell of Dromore, of whom it is said that a Catholic priest who knew him well, and respected him accordingly, said at his grave, "O sit anima mea cum Bedello." It runs to the effect that "a few years before his death he (Bedell) had some severe fits of the stone," and that "the best remedy that he found for it was to dig in his garden till he had very much heated himself, by which he found a mitigation of his pain," and this heat acted, no doubt, on him pretty much as a stoup or a warm bath might. The late Mr. Allarton (or, it might be, some other to me now unknown writer) has told a very similar story of the famous Bishop of Meaux, the "Magnus Bossuetius" of my old Gallican tutor, and like stories are, I think, told of others in the same condition.

2. Describing the medicinal remedies or contrivances of the savages of equatorial Africa, Sir Samuel Baker says ("The Albert N'yanza," vol. ii., p. 274) that "the treatment for headache among all the savage tribes was a simple cauterisation of the forehead in spots burnt with a hot iron close to the roots of the hair."

3. Describing the ecclesiastical arrangements of the Russian Church in his day, and with especial reference to the deposition and incarceration in chains by order of the Czar of one of the best of their metropolitans, Baron von Herberstein, says ("Notes upon Russia," Hakluyt Society, vol. i., p. 54) that "one Daniel succeeded him as metropolitan, a man of about thirty years of age, of a large and corpulent frame, and with a red face, who, lest he should be thought more given to gluttony than to fastings, vigils, and prayers, used on all occasions when he had to perform any public ceremony to expose his face to the fumes of sulphur to make himself pale, *and when he had by this means become thoroughly pale* he would present himself in public"! The italics are mine, and I use them to point out a valuable addition, when pallor is the object to be acquired, to our ordinary cosmetic resources, and ask at the same time if this very practice has not been long recommended, *inter alios*, by Terence or Mænander?

I am, Sirs, your obedient servant,

Auriol-road, W., August, 1887. W. CURRAN.

PASSAGE OF FOREIGN BODIES THROUGH THE ALIMENTARY CANAL.

To the Editors of THE LANCET.

SIRS,—The following case may make a pendant to that of "H.F.S." in your issue of Oct. 15th, as showing the opposite rate of speed in the passage of a metallic body through a child.

On Whit Sunday (May 29th), I was startled by a message that a young patient of mine, aged eight months, had "cut his throat." The messenger, who was a foreign gentleman, drew his hand across his throat so that there might be no mistake. I arrived at 1.30 P.M., and found that the mother had been alarmed at seeing some blood coming from the *inside* of the throat, and that at the same time she had missed the screw and clip [enclosed] which was used for the purpose of compressing the tube of the feeding bottle. I appeased her alarm, and next morning at 7.45 the child passed it, open to the full point just as I forward it. A word of warning to mothers to discard these clips would be useful. A knot in the tube, tightened or relaxed according to circumstances, is sufficient.

I am, Sirs, yours faithfully,

Oct. 25th, 1887. J. B. E.

BURIAL REFORM.

To the Editors of THE LANCET.

SIRS,—Touching this subject, as noticed in your issue of Oct. 15th, and as tending towards full development of the object in view, I wish to raise the following points for inquiry and elucidation.

Among the desired reforms mentioned are: "That the coffin should be of the most perishable and lightest material," and "burial in the plain earth, in conformity with the instructions in the Burial Service—'earth to earth.'" But would not even "compressed pulp" as the material of the coffin in dry earth tend to postpone decomposition? and cannot the coffin be completely got rid of in order that the earth may have full play, and at once, on the body? Are there any valid objections in this country to envelopment of the body in merely some light sheeting, and so interred (simple and primitive), with an additional temporary covering of cloth during transit to the cemetery? Or, if the process of conveyance and religious ceremonies in church require some firmness in the material to conceal from view the outline of the body, could not a wooden coffin be made of separable parts to further these aims, but to be removed after deposition in the grave? Suppose that the bottom of the coffin (of wood or any other temporary firm material), a plank with outline as at present, had at about an inch or less from the edge a thin wooden ridge about three inches high running all round (to keep the upper part *in situ* and prevent escape of fluid from the body), and so forming one part, and the top and sides to form the other, the latter when connected with the former enclosing the ridge and resting on the bottom with a few light iron clamps to retain the two portions firmly together in transit. The body in some light covering could be lowered in this into the grave, and after completion of the ceremonies the upper part (clamps loosened previously) could be drawn up, leaving the body resting on the bottom of the coffin, but free elsewhere for direct contact with the earth. This would deviate but little outwardly from our present system up to deposition in the grave; but beyond this it would thoroughly (the back of the corpse excepted) effect "earth to earth." It would not necessarily entail very early burial; and though an objection might be raised by the friends to the ground falling roughly on the all but exposed body (hardly more unpleasant than the rattle on the hollow coffin), yet a little care in the deposition of the first earth would obviate this natural grievance. The cost would be small, as the upper part of the coffin would be available for any number of burials, while sanitation and transit purposes would be met. The riddance of any kind of coffin seems eminently desirable. What is to be said against the suggestion?

I am, Sirs, yours faithfully,

October, 1887. F. H. W.

REMARKABLE CASE OF LONGEVITY.

To the Editors of THE LANCET.

SIRS,—Should you think the following of sufficient interest, will you insert it in the columns of your journal?

The death is announced of Miss Charlotte Pigot, aunt of the present rector of Whittington, Kirkby Lonsdale, at the Rectory, on Sunday, Oct. 9th. She was born at Alington, in Shropshire, on July 9th, 1785, where her father, Thomas Pigot, Esq., resided, her grandfather being Charles Peplow Pigot, Esq., of Peplow, in the same county. Fourteen years ago, being then eighty-eight years of age, deceased came to the Rectory, as she said, "to die"; but a remarkably vigorous constitution repelled death's attacks, and she lived to this ripe old age in unburdensome cheerfulness. Some years ago deceased lost her eyesight; but every other faculty she possessed up to the very last in a marked degree. The most remarkable feature of this wonderful lady is that she was never confined to her bed for a single day until the last few months of her life, and it was only through the loss of the use of her legs that she ultimately took to bed. Her powers of digestion were most remarkable. Up to the very last her appetite was as vigorous as in the prime of life, eating hard-boiled eggs (ten minutes), pork pie, and Welsh rarebit with the greatest relish, and feeling no evil effects whatever. Her memory, too, was wonderful. On her hundredth birthday she conversed with great avidity upon events that took place in 1795, the particulars of which were present in her mind. She had a room to herself at the Rectory, but always joined the family at meals down stairs. Breakfast was served at 8.30, to which the deceased never failed to put in an appearance; and after the evening meal she would spend the evening with the family until 10.30 in cheerful conversation. Her nephew on her hundredth birthday drove her into the town of Kirkby Lonsdale, which she seemed very proud of. There must be something in the locality of the district which tends to prolong life; for at Heysham, near here, a lady at present survives who is in her hundred and third year. I am, Sirs, yours very truly,

W. H. LEDGARD, L.R.C.P.Ed., M.R.C.S.

Kirkby Lonsdale, Oct. 18th, 1887.

STROPHANTHUS PODS FROM THE NIGER.

To the Editors of THE LANCET.

SIRS,—We have pleasure in forwarding you herewith a specimen pod of an entirely new species of strophanthus from the Niger, just to hand. We have noticed in it that though the pod and seed somewhat resemble those of *S. hispidus*, the foliage, which has also reached us, is quite different. We have so often been asked by medical men to supply samples, that we think it would be of interest to your readers to know they can now obtain pods for materia medica collections.

We remain, Sirs, yours truly,

Lime-street, E.C., Nov. 1st, 1887. THOS. CHRISTY AND CO.

CHEFOO HOSPITAL.

DR. DOUTHWAITE, medical missionary connected with the China Inland Mission, who has a hospital at Chefoo, mentions in a recently published report that though there are a few beds proper for surgical cases, the patients prefer the *k'ang* to any bed. The *k'ang* is a brick platform, six feet wide, raised two feet and a half above the floor, and extending across the room. The top is composed of stone slabs, plastered over with clay, and is warmed by burning grass or other fuel in the flue, which ramifies beneath it. It is covered with straw matting in summer, and padded quilts in cold weather. On these hard, comfortless beds the patients will lie or sit for weeks, quite happy and contented, and really prefer them to the spring mattresses which are provided for those who desire them. One advantage of this arrangement is that the bed can be covered with a clean sheet of whitewash whenever necessary. This necessity arises very often, and the mats the patients have slept on require drenching with boiling water after being used a short time. The reason for this is obvious. The prevailing diseases are those of the skin and the respiratory and digestive organs; but during the spring and summer months remittent fever is most common. "Passion" or anger is, according to the natives, the cause of all classes of disease, from glaucoma to gastro-hepatic troubles. This anger does not cause the people to feel in the least ashamed of themselves, as they consider themselves merely irresponsible victims.

Justitia.—No doubt B earned his promotion by his long tenure as house-surgeon; but the selection of B might surely have been made without any discourtesy to A.

Mr. E. W. Evans.—If the engagement was verbal, and there was no written agreement specifying that written notice must be given, the engagement can be terminated by a proper verbal notice.

Dr. Salvati is thanked for his communication.

VACCINATION AND SMALL-POX AMONGST THE CHINESE.

To the Editors of THE LANCET.

SIRS,—Vaccination in connexion with small-pox having recently been made the subject of some comments in your journal, the following figures may prove of some interest. They are taken from an abstract of a very instructive colonial surgeon's report for 1886, by Mr. P. B. C. Ayres of Hong Kong.

Small-pox Hospital (European), 11 admissions, with one death—i.e., a mortality of 9·1 per cent. Small-pox wards of Tung Wa Hospital (Chinese), 54 admissions, with forty-two deaths—a mortality of 77·7 per cent. In connexion with the European cases it is stated in the report that "most of the cases were of a mild type," but that the Asiatic cases were "mostly of the worst type, unvaccinated, and the majority children." The former set of cases, then, show the work of small-pox amongst what may be taken to be a fairly well vaccinated community, and under skilful treatment; the latter the mortality of the same disease amongst an unprotected race and under Chinese treatment. This question of treatment must, of course, be taken into account in drawing a conclusion. But, on the other hand, it must be remembered that the Europeans are living in, for them, an unnatural climate, and so far would probably be in a less favourable condition of health to withstand the action of the disease than the Chinese, who, in spite of their filthy mode of living and the apparent poverty of their diet—I am alluding to the native labouring classes in European settlements—are a hardy race. It may be mentioned in passing that a few of these Chinese are vaccinated; for it is mentioned in the above report that 2206 successful vaccinations were performed during the year at the Tung Wa Hospital. Judging, however, from my somewhat limited experience on the Chinese coast as ship surgeon, where I had at different times a considerable number of coolies under my charge, the proportion so protected must be minute. In short, after every circumstance has been taken into consideration, the figures given will, I think, be allowed to form an additional argument, if any be required, in favour of the prophylactic efficacy of vaccination.

I remain, Sirs, your obedient servant,

Norland-square, W., Oct. 29th, 1887. ALEX. G. R. FOULERTON.

"ABUSE OF HOSPITALS BY THE WELL-OFF."

To the Editors of THE LANCET.

SIRS,—Here is another authentic case. A married lady, one of my own relatives, without family and spending £70 or £80 yearly on dress, consulted a "lady's doctor" (now deceased), who after a while said she must undergo some surgical treatment, for which he persuaded her to go into one of the largest of the London hospitals to which he was attached. This she did; and was in the hospital several weeks. He made no stipulation that a donation or payment of any kind should be made to the hospital. On subsequently learning these facts and ascertaining that this fashionable lady had positively not made any gift to the hospital, although I know that she and her husband had an income of about £500 a year, I took £10 out of my own pocket and made the husband enclose it to the treasurer of the hospital as an acknowledgment for services rendered and costs incurred. In the above case I think the surgeon was blameworthy for permitting the hospital funds to have been so abused.

I am, Sirs, yours truly,

Oct. 27th, 1887. M.D.

"ANTIPYRIN IN MIGRAINE."

To the Editors of THE LANCET.

SIRS,—Kindly allow me to send you a notice from Germany about "Antipyrin in Migraine." In your issue of the 15th I read a very interesting case from Dr. Edward Warren-Bey of Paris, of his having treated a lady suffering from migraine with antipyrin very successfully.

May I tell you that in Germany treatment with antipyrin in cases of migraine has been for some time past very successful; that all our medical men prescribe this medicine in migraine. The dose which we give is half a gramme. It is best to give it in the aura, before the attack comes on. For instance, when a patient feels the evening before that she is likely to have an attack the next morning, she should take antipyrin when she goes to bed, and when she awakes the next morning and feels, notwithstanding this, that the migraine will come, she must take a second dose, remaining in bed for one or two hours, and in most cases the attack of migraine will be suppressed. In my own practice I have successfully treated many cases. Antipyrin is not only a very good remedy for migraine, but many practitioners have used it for tabes dorsalis (especially for the pains) with very satisfactory results. The dose in this case would be the same as for migraine.

I am, Sirs, respectfully yours,

Dresden, Oct. 30th, 1887. ARTHUR BERTHOLD, Dr. Med.

"LINIMENTS FOR CLUB USE."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "Club," I beg to say he will find the following formula a cheap and useful liniment for club patients: ℞ Sp. terebinth., ʒviii.; liq. ammon. fort., sapo mollis, aa ʒvi.; aquæ, O.iv. Ft. liniment. Dissolve the soap in boiling water; when cold, add the turpentine and ammonium; when mixed it will form on shaking a very nice emulsion without any deposit of soap. Of course, the liniment can be made any strength by increasing or decreasing the ingredients.

I am, Sirs, yours truly,

Andover, Nov. 1st, 1887. S. B. FARR.

*** Other correspondents offer the same prescription.—ED. L.

"HOME FOR INEBRIATES OF LIMITED MEANS."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Wilson's question in your last issue, I can highly recommend the British Women's Temperance Home. The terms are from 7*s.* 6*d.* to £1 10*s.* per week. The Matron, The Mount, Perry-rise, Forest-hill, would answer inquiries.

I am, Sirs, yours faithfully,

New Wanstead, E., Oct. 31st, 1887. ALICE E. G. HAWKES.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Post-Graduate Lecture

ON

RHEUMATISM,

Delivered at Charing-cross Hospital,

BY JULIUS POLLOCK, M.D., F.R.C.P.,
SENIOR PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—I am much honoured by having been requested to give the first of this course of lectures at Charing-cross Hospital. I feel at the same time that I have a great responsibility, for in an undertaking like the present a good start is all-important, and anxious as I am to to do my best, and with the keenest interest in the success of the course, my efforts may, and probably will, fall far short of my desire.

Before entering upon the special subject that I have been requested to treat, it is, I think, incumbent upon me to say a few words by way of introduction. There can be little reason to doubt the need of such a course of lectures as this, and the success of a similar plan of teaching in America, in Edinburgh, in Leeds, and in other places, has shown that under proper direction and favourable auspices such a mode of imparting instruction has met with the entire approval of those for whom the lectures are intended. We are, or ought to be, all of us students in the best sense of the word to the end of our lives; and with the vast amount of knowledge to be acquired, with the constant and important advances that are continually being made in pathology, the means of diagnosis, and the treatment of disease, it is quite impossible that the few years of study comprising the medical curriculum should suffice for the acquisition of a complete and final grasp of such vast subjects as medicine and surgery. Seeing, then, how great the advantages of a post-graduate course of lectures must be, it appears strange that such a scheme should not always have proved successful, but a little thought will show how important are certain details in the arrangement of the course, in order that it may meet the requirements of those for whom it is especially intended. A want of proper attention to such details has in some instances led to comparative failure. The lectures must be given at an hour when the busy practitioner is best able to attend. They must be essentially practical in character; and the subjects should be selected by those who desire to learn, rather than by those who are willing to teach. It is also desirable, in order to maintain the independence of the class, that the lectures should be self-supporting, and a moderate fee paid for the course. Another very important point is the hearty co-operation of the whole staff of a hospital in the work of instruction. It gives a higher tone to the task, a variety to the teaching, a lightness to the labour. Under conditions such as these there is every reason to hope that our post-graduate course of lectures may become popular and attractive, and obtain a permanent footing amongst the various means that exist for enlarging our knowledge and increasing our usefulness.

Let me now pass to the subject of my lecture. I have certain drawbacks to contend against to-day, which I do not allude to by way of complaint, but that you may know I have not overlooked them. In the first place, there is little or nothing new to tell you about rheumatism. No fresh light has been shed upon its pathology or treatment during the last few years, and I fear lest what I have to say to you may be "as tedious as a twice-told tale." Then, again, I am badly off in the matter of illustration. My subject is one that does not carry specimens or diagrams. Nor are we able at will to command the presence of a certain number of cases of rheumatic fever in the wards. At the present time there is but one, and he is convalescent. Such are my difficulties, and I am sure you will bear kindly with me. But to proceed. There are two forms of rheumatism, the articular and the muscular; and although they both are known under the common term "rheumatism," they are really, I believe, two separate and distinct disorders, with but little in common except their name. Articular rheumatism, as its name implies, is essentially an affection of the joints, very frequently associated with inflammation of the pericardium, endocardium, and other serous membranes, the structure of which so closely resembles the synovial. There is usually fever and marked constitutional disturbance. The disease, when uninfluenced by remedies, pursues a tolerably definite course, and has a strong tendency to wear itself out in time—say "six weeks," according to the first Dr. Warren. Its main features are those of an acute febrile attack, with local lesions. Muscular rheumatism, on the other hand, is a much more indefinite complaint, affecting the muscles, aponeuroses, and other fibrous structures, rarely accompanied by fever, never implicating the heart, and of very uncertain duration. Both these forms of rheumatism are full of interest, and will repay careful study; but either is a large subject, and it would be impossible to do justice to the two diseases in one lecture, so I propose, if you will allow me, to confine my attention this afternoon entirely to the articular form, which from its greater pathological importance may well claim precedence. This disorder occurs in three well-marked forms—the acute, the subacute, and the chronic. The first two are often spoken of as "rheumatic fever," and I shall not scruple to avail myself of this term to avoid tautology. Perhaps the subacute form, in which the temperature ranges from 99° to 102° F., is that most commonly seen, especially in hospital practice. It differs from the more acute variety simply in degree; all the symptoms are less severe, a fewer number of joints are implicated, and perhaps there is less chance of cardiac mischief. But it is quite as tedious as the acute form, and relapses are not uncommon. In chronic articular rheumatism there is generally no pyrexia, and I believe it is not unfrequently confounded with other kinds of joint disease. It is recognised without difficulty by the number of joints that are affected at the same time, and by the wonderful influence that salicylate of soda exercises over it. I call to mind one case of this chronic form, which came under my notice in the very early days of the salicylate of soda, and in which for nearly a month I tried every remedy for rheumatism that I could think of; at last I used the salicylate of soda and cured my patient in two days.

I propose to pass lightly over the ordinary phenomena of an attack of rheumatic fever, which are probably as familiar to most of you as they are to me; the symptoms of having "taken cold," the more or less pyrexia, the profuse and acrid sweat, the swollen, painful, and tender joints, the occasional metastasis, and the not infrequent implication of the heart, which latter complication, if it be a complication, and not, as some German authorities have held, the very essence of the disorder, are the more likely to occur in inverse ratio to the age of the patient. But there is a remarkable condition that sometimes arises during the course of an attack of articular rheumatism to which I desire especially to call your attention. I allude to what is known by the name of "hyperpyrexia." Now this state of high fever is not unknown in other diseases; it occasionally accompanies typhoid and scarlet fever; it is the very essence of *coup-de-soleil* or sunstroke, and is met with in various diseases of the nervous system; "but it is in connexion with acute rheumatism that it has attracted most attention and is most frequently encountered. Curiously enough, it is not only the more severe attacks of the disease that drift into hyperpyrexia; comparatively mild and subacute cases, which appear to be doing well, will now and then take this remarkable course. The symptoms of hyperpyrexia are very characteristic and well marked. The temperature, which in ordinary cases of rheumatic fever ranges from 100° to 103°F., or thereabouts, without any apparent reason begins to rise, and may ultimately attain the height of 110°, or even more; at the same time the joint affection subsides, pain is no longer complained of, and the patient often expresses himself as better just as the most serious symptoms are coming on. In most cases, but not invariably, the profuse sweating ceases; the skin becomes dry, harsh, and intensely hot to the touch; very frequently a crop of sudamina breaks out upon the neck, chest, and abdomen (which latter symptom I have learned to look upon as a very unfavourable sign); the tongue becomes dry and brown; there is great thirst, with complete loss of appetite; the breathing is rapid, the pulse very quick and generally weak; the patient is tremulous and restless, with a suffused and 'ferrety' appearance about the eyes, delirious at night, but often fairly sensible in the daytime. The delirium is generally of a low, muttering kind, not unlike that of delirium tremens, though occasionally there is some excite-

Digitized by Google

ment. Unless the disease takes a favourable turn, or relief can speedily be given, death ensues in a day or two, apparently from mere hyperpyrexia."[1]

The occurrence of hyperpyrexia would appear to depend upon the nervous system being attacked by the rheumatic poison; at least this was the view that I took of it ten years ago, and which has since been abundantly confirmed. Dr. Maclagan says:[2] "Admitting the existence of a thermic centre, whose function it is to control heat formation and prevent undue rise of temperature, we have no difficulty in certain maladies and injuries in attributing the increased body heat to interference with that function. The temperature rises because the reins are slackened. The sequence of events seems to admit of no other explanation. Carrying out this line of argument, we cannot fail to see, not only that the rise of temperature thus induced must be directly as the extent to which heat inhibition is impaired, but that paralysis of the thermic centre, by abolishing inhibition and leaving heat production in uncontrolled possession of the field, must lead to hyperpyrexia. And the more we consider the pathogenesis of febrile heat, the more apparent does it become that impairment of inhibition is a much more likely cause of hyperpyrexia than is direct stimulation of heat production. Heat inhibition remaining unimpaired, tissue metabolism could scarcely cause those very high temperatures which characterise some cases of hyperpyrexia. Heat inhibition being paralysed, there is no difficulty in seeing that the temperature cannot fail to rise, and to go on rising, so long as tissue metabolism and heat production continue. All cases of hyperpyrexia we therefore regard as being probably of neurotic origin—as due to some cause which exercises a paralysing influence on the thermic centre. Pyrexia may result either from increased production or defective inhibition, but marked hyperpyrexia is probably due only to defective inhibition. In the cases hitherto instanced there has been a direct lesion of the nervous centres to explain the paralysis of the thermic centre and the consequent rise of temperature. Other cases there are, however, in which the evidence of paralysis of that centre is equally well marked, in which hyperpyrexia is pronounced, but in which the sequence of events by which it is brought about is not so apparent."

Now what is the etiology—what are the causes of rheumatic fever? These may, very properly I think, be divided into two—"predisposing" and "exciting." This part of my subject has given rise to much speculation and conjecture, and various theories as to the pathology of acute rheumatism have been broached. Is there a special poison, and if so is it introduced from without, as in the case of small-pox, typhoid fever, or ague? or is it manufactured within the body, as in gout or uræmia? Dr. Maclagan has advocated the view that the poison of rheumatic fever is malarious in origin, and although I cannot agree with this, it was a very "happy thought," for it led him to try salicin in the treatment of the disease, and was the means ultimately of introducing the use of salicylate of soda, the value of which is now universally acknowledged. By some authorities the "germ" theory has been entertained, and Professor Pel of Amsterdam, thinks that "it only wants the discovery of the specific micro-organic cause of the disease in the inflamed serous membranes to render the present presumption of its specific origin a certainty."[3] But I do not "cotton" (to use a homely phrase) to the theory that the poison of acute rheumatism is introduced from without. All the evidence appears to me to point to the conclusion that it is manufactured *within* the body. This has been clearly proved to be the case in gout by Sir Alfred Garrod; and Dr. Lauder Brunton has called attention to certain remarkable poisons that are formed during the peptonising of proteids within the living body, which suggests the possibility, to say the least of it, of the *materies morbi* of rheumatic fever being formed during the process of digestion or metabolism. Whether it may be lactic acid, an old idea recently revived by Dr. Fagge, or any other kind of acid, I cannot say. We know that a profuse and acrid sweat accompanies the disorder, and looks like an effort of nature to eliminate the poison; but we also know that no amount of alkalies will neutralise the mischief. Unsatisfactory as it may be, we must, I think, admit that the particular substance the presence of which in the blood predisposes to an attack of acute rheumatism has yet to be discovered.

The liability to rheumatic fever is not the same at all ages. It is amongst the young that the disease is most prevalent, though mere infants do not seem to suffer. Perhaps the most common time of life for an attack is between the ages of ten and thirty, though it may occur in younger and older persons. It is very unusual to meet with a first attack of articular rheumatism after fifty years of age, and even those who have had the disorder ultimately outlive their liability to be attacked by it. Youth, then, must be reckoned as among the predisposing causes of acute rheumatism. A previous attack has been also supposed to increase the liability to the disorder, but about this there is some doubt. The very fact that in course of time the tendency to the complaint is lost would seem to contradict it. Some ten years ago I was the only person who dared to disbelieve the dictum that former attacks predisposed to the disease; but I find now that the late Dr. Fagge, in his work on Medicine, takes the same view. Loss of health or debility in any form no doubt increases the liability to acute rheumatism. It also seems to be inherited, and in some persons there is such a strong tendency to the disorder that the slightest exposure to wet and cold, or to cold only, will bring on an attack, and occasionally no exposure at all can be traced. Other persons are much less liable to rheumatism, and only the most disastrous circumstances will produce the disorder. A large number of the community escape the disease altogether, no matter to what amount of wet and cold they may be exposed. "The most important exciting cause, perhaps the only one worth considering, is exposure to cold, and especially to cold and wet. Sleeping in a damp bed with insufficient clothing, remaining in wet clothes, sitting in a draught of cold air when heated—in fact, getting a 'chill' in any way, will often induce acute rheumatism in those that are disposed to it. Possibly it is the check thus given to the eliminating functions of the skin that determines an attack of the disease. It may be well to mention here that it is wet *and* cold that are so injurious; and if anyone find himself in a damp bed, he may minimise the mischief, perhaps save himself from any harm, by heaping on plenty of clothes, or by getting rid of the sheets and sleeping between the blankets only."[4] In the same way, if we happen to get wet through from any cause, we should keep ourselves warm by sharp exercise until we can get a change of clothing, which ought to be effected at the earliest possible moment.

It is not often that we have the chance of making a post-mortem examination on a case of rheumatic fever during the height of the joint inflammation, but occasionally a case proves fatal from cardiac complications or hyperpyrexia. We then find that the affected joints are more or less vascular, especially about the synovial fringes, and coated with a sticky, altered synovia. Sometimes there is effusion, but more commonly not, because the joint mischief is apt rapidly to subside upon the occurrence of any fatal complications. It is said by Sir Alfred Garrod that no ulceration of the cartilages takes place in true articular rheumatism, even after repeated attacks of the disease; and very rarely, if ever, is pus found in the joints. When a case has proved fatal in consequence of cardiac disease, the post-mortem appearances will be in accordance with the mischief that has arisen during life. When death occurs in consequence of hyperpyrexia, we shall probably find evidence of pericarditis in about half the number of cases. Cardiac complication is not an essence of the high temperature, but only an occasional accompaniment. The post-mortem appearances in hyperpyrexia will generally include a vascular condition of the brain and meninges, a dark and congested state of the lungs; the liver and spleen are friable and easily broken down, and the kidneys usually congested. The blood is tarry and fluid, but the muscles are remarkable for their bright-red colour. These changes, it will be noted, are simply the result of the high fever. The odour of such cases, even when recently examined, is most offensive.

The diagnosis of acute rheumatism is generally so simple and easy that I do not halt here to make any remarks on the subject. The prognosis is eminently favourable as far as the mere issue of the affection of the joints is concerned; but it

must be guarded (1) in reference to possible cardiac mischief, and (2) the chance of hyperpyrexia, which latter, however, is but a remote contingency. Heart disease is more liable to occur in children; hyperpyrexia in adults. In the chronic forms of true articular rheumatism the prognosis is very favourable.

I now come to the last and most important part of my subject—the treatment of rheumatic fever. A few years ago this was most unsatisfactory. I have seen alkalies, quinine, blistering, and other reputed remedies tried in a large number of cases, alone or in combination, but without being at all impressed by their value; and well might Sir William Jenner, when President of the Clinical Society, express the doubt and uncertainty with which he used to approach the treatment of articular rheumatism under the old *régime*. But some ten or twelve years ago a new and improved method of dealing with the disorder came into operation; and it is only due to Dr. Maclagan that he should have the credit of having been the first to use salicin as a remedy, which ultimately led to the introduction of salicylate of soda, one of its derivatives. I cannot say that I have had much success with salicin, though I have tried it in a number of cases, but he must be blind indeed who cannot perceive the great value of the soda salt. There may be some doubt as to whether its use shortens the duration of rheumatic fever, but beyond question it robs the disease of some of its most painful symptoms. In a few days, sometimes hours, the temperature is brought down, the inflammation and pain in the joints subside, and the patient is in most cases practically convalescent. It is not claimed for salicylate of soda that it will prevent the occurrence of heart complications, or even hyperpyrexia, but it lessens the chance of either mischief by rapidly reducing the fever. It must also be borne in mind that the drug is not an absolute specific. Where shall we find one? It fails to relieve or cannot be tolerated every now and then. But this is no more than what happens with quinine in ague, or iodide of potassium in syphilis. Salicylate of soda sometimes produces sickness, deafness, tinnitus aurium, and a peculiar kind of cerebral disturbance; but these disagreeable effects quickly disappear on a discontinuance of the drug, and seldom return upon its resumption after a short interval. The salicylate has been charged with producing serious cardiac depression, and even causing sudden death; but the evidence on these points is not very clear, and personally I have never witnessed any such effects. In treating a case of articular rheumatism, the salicylate of soda may be given in doses of ten, twenty, or even thirty grains every two, three, or four hours, according to the severity of the symptoms and the effect produced. Where there is evidence of great acidity, some alkali (five to fifteen grains of the bicarbonate of potash) may be usefully combined with each dose of the salicylate, which is best given in some aromatic water to conceal its somewhat acrid taste. It is important to keep up the action of the drug for some days after the disappearance of the fever, as the premature disuse of it is apt to lead to a return of all the symptoms—a so-called relapse. Towards the close of a case of rheumatic fever, the joints are not unfrequently left rather swollen and painful; it is then that iodide of potassium (internally), and iodine paint (externally) are so useful. When quite convalescent, the patient should have tonics, and especially steel and quinine; and if rheumatic pains linger, the salicylate of quinine, in five-grain doses, three times a day, is often of much service. Other salts of salicylic acid will probably be found useful in the treatment of rheumatism; and lately a new preparation, "salol" has been introduced. It is a salicylate of phenol and has been used a good deal in America, with, I believe, satisfactory results. But it may be asked, What is to be done in those cases of articular rheumatism in which the salicylates are not successful? Well, it is unfortunate when this happens, but we may fall back upon large doses of salicin, upon alkalies, or upon the excellent alkaline quinine prescription of Sir Alfred Garrod. Quinine and bicarbonate of potash are rubbed up together with a little mucilage and some aromatic tincture, in such proportions that each ounce and a half of the mixture contains five grains of quinine (in the form of carbonate) and thirty grains of potash. This dose may be given every four hours for as long as may seem desirable.

Of course, all cases of rheumatic fever must be kept in bed, and properly dieted. The most suitable nourishment in the earlier stages is the usual beef-tea and milk "fever" diet, but to this may soon be added some farinaceous food, eggs, and afterwards fish. Rheumatic fever is a disease of debility, and it is very desirable to keep up the strength of the patient; but in some cases the too early resumption of meat has seemed to be followed by a return of the rheumatism. Further information on this point would be of value. Stimulants are not absolutely necessary, nor often needed, in cases of articular rheumatism; but they may be required at times, and should be administered in accordance with the condition of the patient. The bowels should receive attention, but no active purging is required, especially as the movements necessitated by any action of the bowels are attended with considerable pain in severe cases. On the other hand, opium or morphia, which may well be used hypodermically, is often of great service, alleviating the pain in the joints and allowing the patient to get some sleep. When cardiac mischief arises in a case of acute rheumatism, it should be treated in accordance with the plan adopted in such cases, the consideration of which is outside my subject. I must, however, say something about the treatment of hyperpyrexia, a matter of much interest and importance. It is unfortunate that in this severe condition, where most we want its aid, the salicylate of soda, though it was originally introduced as an antipyretic, should entirely fail. Nor can I say much that is favourable of any other of the reputed febrifuges, such as quinine, antipyrin, &c. In truth, we are driven, in the treatment of hyperpyrexia, to the application of external cold, and although some years ago I expressed a very doubtful opinion as to the efficacy of this method, a further knowledge of the subject has led to a considerable modification of my original views. There is now, I think, no question that the careful and judicious use of the cold bath or cold pack holds out the best chance of saving life in these truly formidable cases. The most important precaution would seem to be that the application of cold should be gradually and cautiously applied so as to avoid shock. This may be accomplished by placing the patient at first in a bath the temperature of which is not much below 80°F., and gradually reducing the temperature until the desired effect is produced. This bath may have to be repeated more than once perhaps, and the use at the same time of injections of ice-cold water into the rectum may be of service. Where a bath is not available, or thought to be undesirable for any reason, the cold pack may be tried. In cases where ice is not used, the patient's body and limbs are wrapped closely in a single sheet, which has been previously wrung out of cold water (temperature 50° to 60°). A blanket is then thrown loosely round him, and he is allowed to remain undisturbed for about half an hour, when the same process is gone through again, and repeated until the temperature is sufficiently reduced. When the ice pack is employed, a hip bath, or other suitable receptacle, containing a few gallons of water, in which some large pieces of ice are floating, is kept by the patient's bedside, and his body and each limb are separately wrapped in pieces of old sheeting which have been wrung out of the iced water, each piece being renewed as often as it begins to feel warm to the hand. No other covering of any kind is put over the patient. In this way the temperature may be very rapidly reduced, and it is necessary to be careful that it is not brought too low. It should not be allowed to fall below 99° F. Amongst many others, two cases have recently been reported which tend strongly to show the value of external cold in the treatment of hyperpyrexia. One is by the late Dr. Carrington, at a meeting of the Clinical Society on Feb. 25th last, and the other by Dr. Frederick Taylor, in THE LANCET of March 12th, 1887.

METROPOLITAN POLICE SURGEONS' ASSOCIATION.—At a meeting held on Nov. 3rd, the following officers and Council were elected for the ensuing year:—President: A. O. Mackellar, F.R.C.S. Vice-Presidents: Thos. Bond, F.R.C.S.; Roderick Macdonald, M.P., L.R.C.P. Treasurer: George B. Phillips, M.R.C.S. Hon. Secretaries: H. Nelson Hardy, F.R.C.S. Ed.; J. H. Waters, M.D. Council: Alex. Forsyth, M.D.; D. S. Downes, L.K.Q.C.P.I.; T. C. Murphy, L.R.C.P.; E. K. Hinchin, L.R.C.P.; S. Mills, M.R.C.S.; Geo. Pearse, L.R.C.P.; J. Hammersley, M.R.C.S.; E. C. Barnes, M.R.C.S.; F. J. Bucknell, M.B.; M. Brownfield, L.R.C.P.; G. E. Yarrow M.D.; W. H. Roots, M.R.C.S. This Association has made a good start, with the entire approval of the late chief surgeon and the present chief surgeon, as also of the Commissioners of Police. It is remarkable that such an association has not been formed before.

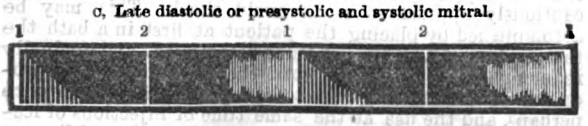
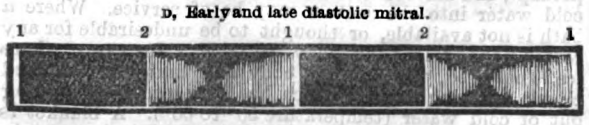
ON OBSTRUCTIVE MITRAL MURMURS.[1]

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.

OBSTRUCTIVE mitral murmurs are generally regarded, I believe, as presenting two well-marked varieties, of which the one, named indifferently presystolic or auricular-systolic (Fig. C), occupies the latter part of the diastolic period running up to and culminating in the first sound of the heart, while the other is an ordinary diastolic murmur (Fig. A) commencing from the second cardiac sound, and dying away in the course of the diastolic period. These two murmurs may occur independently of one another or in association, and in the latter case the earlier murmur may either die out before the later murmur begins (Fig. D), or the two may meet and blend (Fig. E), so that the whole period of the diastolic silence becomes occupied by a continuous sound.



A, Early diastolic and systolic mitral.



B, Mid-diastolic mitral.

C, Late diastolic or presystolic and systolic mitral.

D, Early and late diastolic mitral.

E, Entire diastolic mitral.

F, Entire diastolic and systolic mitral.

G, Entire diastolic mitral running off from the reduplication.

M, Hæmic pulmonic murmurs.

The so-called presystolic murmur is the more common, the more characteristic, and the more interesting of the two. It commences somewhere in the diastolic period, varies in its duration (being sometimes very short, often much prolonged), is singularly rough in character, and usually increases in power from its origin to its close in the first sound of the heart. Various fanciful, and I think mostly meaningless, combinations of letters have been devised to represent its peculiar quality. It closely resembles the trilled "R," or the sound of a saw slowly worked, and its gathering force and explosive termination in the first sound remind one of the breaking of a wave in the hollow of a rock. It is characteristic of the presystolic murmur that (notwithstanding its roughness and loudness as conveyed by the stethoscope) it is usually audible over a very limited area, the centre of which is a little to the right of and above the apex beat; and is inaudible, or at most very slightly heard, in the axilla, or at the angle of the scapula. So far as I know, this murmur, strikingly characteristic as it is now universally acknowledged to be, was not differentiated from the systolic mitral murmur by the older writers. As a student and young physician, I certainly knew nothing about it, and am sure that I (and I believe all my colleagues) regarded it as systolic mitral. I may add that I have always suspected that one chief ground on which it was formerly taught—that in certain forms of heart disease the pulse at the wrist was sensibly delayed—was this prevailing tendency to confound the two chief mitral murmurs.

The early diastolic mitral murmur, like the murmur of aortic regurgitation, runs off from the second cardiac sound, and tends to die out in the diastolic silence. It may generally be well heard in the mitral area, or in the situation which the presystolic murmur mainly effects. As Dr. Balfour remarks, its seat of maximum intensity is not uncommonly the junction of the left fourth cartilage with the sternum; and it may sometimes be heard here dissociated from its presystolic companion. This murmur is not unlike the murmur of aortic regurgitation, but is generally, I am inclined to think, rather shorter, rather more rough, and more sustained. It is rarely, however, as rough as the presystolic murmur, and I should be inclined to liken its sound to that of the untrilled "R." That it may be confounded with the diastolic aortic murmur, even by presumably competent observers, is certain. Only recently in a patient whom I exhibit this evening, a murmur of this kind, which near the apex blended with a loud presystolic murmur, was heard alone over the cartilage of the left fourth rib, and was regarded as a diastolic aortic murmur by one of my colleagues. And a few years ago I had under my care a patient between thirty and forty years of age suffering from cardiac disease, of which he died, who presented congestion of the face, general anasarca, hæmoptysis, and other phenomena generally present in the later stages of mitral disease, and whose sole local sign of cardiac defect (in addition to the fact of some degree of hypertrophy and dilatation) was a diastolic murmur audible only at the apex of the heart. I came to the conclusion, not without some misgiving, that the symptoms were all due to mitral obstruction. But the post-mortem examination showed that I had been deceived; for the mitral orifice was absolutely healthy, and the aortic valves were contracted and allowed of regurgitation. Of course, it is only those aortic regurgitant murmurs which are inaudible over the base of the heart that can possibly be confounded with diastolic mitral murmurs.

Dr. Dickinson calls special attention to a third variety of diastolic mitral murmur, to which I have also given much consideration, and which, if I recollect right, he considers to be the diastolic mitral murmur formerly recognised by Hope and others. I am inclined to think with Hope that Laennec's diastolic mitral murmur was the murmur of aortic regurgitation, and that his own was either that or the diastolic mitral just described, and not the murmur I am about to discuss. The third murmur occurs isolated in the diastolic period (Fig. B), and for the most part nearer to the second sound than to the first. I believe it is often regarded as a simple reduplication of the second sound. But it differs from the lagging factor of the normal second sound, in the facts that it is of longer duration than the second sound, that it is only to be heard in the region which the presystolic murmur affects, and that it occurs independently of any reduplication of the second sound audible at the base of the heart. The murmur is generally feeble, but varies in duration, and when more than usually prolonged presents obvious traces of the presystolic trill. The rhythmical relations of this murmur and the two sounds of the heart may be represented by a dactyl, of which the first syllable corresponds to the first sound, the second syllable to the second sound, and the third syllable to the murmur. They are better represented if the final syllable of the dactyl be made long instead of short. They may also be aptly represented by the word γεγραφα, which a distinguished colleague of mine used some years ago in illustration of such a case. I do not

[1] Read before the Medical Society of London on Monday, Nov. 7th.

Digitized by Google

know what his present views of this special murmur may be, but at the time to which I refer I believe he regarded the case of which he used this illustrative word as one of simple reduplication of the second sound. The case, however, had been under my observation for several years, and several times in the hospital under my care. It was one which I regarded during the whole of this period as an example of obstructive mitral disease, but in which, while the presystolic murmur was never audible, the short murmur following the second sound near the apex and undistinguishable at the base was always present, and in which I was able to trace the gradual enlargement of the right side of the heart, and the consequent development of a regurgitant tricuspid murmur and its permanent establishment.

The three murmurs above described (which might, I think, be conveniently termed the early, the mid, and the late diastolic mitral murmurs respectively) may exist either separately or combined; and in the latter case may constitute a continuous but uneven murmur, beginning from the second sound, ending with the first, and filling up the whole of the diastolic period; so that the acoustic phenomena of the heart as presented at the apex shall consist only of a series of alternate prolonged roars and briefer periods of silence. (Figs. E and F.) There seems to me no reasonable doubt that these three murmurs, although they frequently occur independently of one another (so frequently, indeed, and so characteristically as to demand individual description and separate recognition), are only parts of a potential murmur filling up the whole of the diastolic period; or, in other words, that they are the fitful, and in a sense accidental, roarings of a continuous torrent. This view seems to me to be confirmed (if confirmation be necessary) by two easily observed facts. The one is, that each one of the murmurs is liable to come and go as no other organic cardiac murmur comes and goes, and that they are liable (especially the latter two) to alternate with or to replace one another. The other is that, although the earlier two sounds are often feeble and somewhat indeterminate in character, when they blend with one another and with the presystolic murmur and become louder, they present all that vibratile roughness of quality which is so characteristic a feature of the generally more noisy and obtrusive member of the firm. In the case of the patient already referred to in the adjoining room, and in whom the condition of the prolonged diastolic murmur has varied somewhat from time to time, I observed on one occasion (and those who were with me and examined her will confirm my statement) that the roughest and loudest portion of the whole-length diastolic murmur was its middle half (Fig. F). I have observed the same thing in other cases.

There are one or two matters in connexion with mitral obstructive disease and the murmur it occasions to which I should like to advert.

The condition of the second sound of the heart in these cases has always been a subject of interest and study. It need scarcely be said that in mitral obstructive disease, as well as in mitral regurgitant disease, and indeed in all affections which oppose an obstacle to the transit of the blood from the pulmonary artery to the left side of the heart, and in which consequently the right ventricle becomes enlarged and the pulmonary artery dilated, the second sound over the pulmonic area becomes accentuated, while that over the aortic area either remains unchanged or undergoes enfeeblement. Further, it is generally recognised that in cases of mitral obstruction there is a marked tendency to reduplication of the second sound. As regards the actual or relative enfeeblement of that portion of the second sound due to the aortic valves, it is obvious that if there be such enfeeblement over the aortic area (where this sound is always best heard), there must be proportionate enfeeblement at the extreme apex of the left ventricle, and that occasionally it will be heard with difficulty at that spot. It is said, indeed, that in some cases it becomes inaudible there. No doubt such cases are met with, for one occasionally observes the extinction of the second sound in this locality in other forms of heart disease. But I cannot call to mind any example of mitral obstruction in which I have been unable to detect the second sound at the apex. The only case, indeed, in which it has seemed to me possible to ignore its presence is that in which the enfeebled second sound is lost in the noisy commencement of a prolonged diastolic mitral roar. The reduplication of the second sound is certainly a common accompaniment of mitral obstruction; but it is a very variable phenomenon, and is apt to come and go in the same case. The reduplication seems due to the lagging of the aortic valves. The second sound is of necessity loudest, and its reduplication necessarily most distinct at the base of the heart in the neighbourhood of the valves. Reduplication of the second sound, audible only at the apex, is therefore an impossibility. It is for this reason, amongst others, that the mid-diastolic mitral murmur, which may simulate reduplication and has been mistaken for it, cannot be of pulmonic or aortic origin. But reduplication of the second sound in cases of mitral obstruction is not infrequently audible at the apex as well as at the base; and an interesting example of this fact has been more than once furnished by the patient already once or twice referred to, in whom the second sound is sometimes single, sometimes double, and in whom, when such reduplication is present, the prolonged diastolic mitral roar starts from the repeated second sound, thus leaving the second sound at the apex apparently normal, and allowing of a momentary interval of silence between it and the murmur. (Fig. G.) I believe that this phenomenon is always observable when the second sound is reduplicated, and the mitral murmur is of the early diastolic kind.

The presence of a thrill over and about the spot on the surface of the chest at which the heart's apex impinges has always been recognised as a characteristic accompaniment, not only of the presystolic murmur, but also of the noiseless rush of blood through a contracted mitral orifice. There can be no doubt, I think, that an apex thrill is in a very large proportion of cases diagnostic of mitral obstruction, and that it is generally due to the rhythmic vibrations of the blood entering the ventricle from the auricle, on which also the characteristic rough murmur depends. By most observers it is said distinctly to occur while the presystolic murmur proper is, or should be, in progress and the contraction of the auricle presumably is taking place. Dr. Galabin's cardiographic tracings seem quite to confirm this relation. But when the rough murmur occupies the whole of the diastolic period, the thrill also (as nearly as may be) is equally lengthy; and when the murmur is roughest in the mid-diastolic period the thrill is most marked during the same interval. Yet I am bound to admit that, so far as I can make out the only, or at any rate the most marked, thrill seems occasionally to accompany the ventricular systole. In a case at present under my care in which a hæmic pulmonary murmur is associated with a double mitral murmur, the apex thrill was certainly at one time mainly systolic. But the heart was beating rapidly (over 100 in the minute), and the thrill (as I think the cardiographic tracing confirms) was due to the successive rises and falls which even in health are apt to appear on the broad summit of the excursion representing the cardiac systole.

The association of a true regurgitant or systolic mitral murmur with an obstructive murmur at the same orifice is by no means uncommon. In most cases the first sound of the heart terminates the one and starts the other (Figs. C and F); in other words, a presystolic murmur and a systolic murmur are made continuous by the intervention of the first cardiac sound. Under these circumstances the two murmurs are generally, I believe always, absolutely distinct from one another, both in relation to the apex beat and the pulse, in the quality of their sounds, and in respect of the areas over which they may be respectively best heard. The presystolic sound definitely precedes the apex beat, but runs up to it, and equally definitely precedes the carotid pulse; while the commencement of the other coincides accurately with the apex beat and the pulse. The presystolic murmur is always rough, and generally increases in roughness and loudness until it blends with the first sound; the other, with very rare exceptions, is either musical or blowing and dies away into silence. Indeed, the sudden transition from the one kind of sound to the other is a very striking phenomenon. I admit that occasionally at the apex of the heart a short rumbling murmur is heard about the beginning of the ventricular systole, the exact relations of which it is difficult to determine; and that I am disposed at times to regard such brief murmurs as systolic, at times as presystolic, at times as ill-defined combinations of the two. My belief, however, is that (as the peculiar roughness of such sounds and their comparatively abrupt termination seem to imply) they are really presystolic. Again, the presystolic murmur has before been

Digitized by Google

pointed out) is heard over a very small area, and is not only generally audible in the axilla, below the angle of the scapula and at the base of the heart, but often fails to reach even the true apex. On the other hand, the mitral systolic associated with it may not only be heard where the presystolic is also heard, but extends in a greater or less degree into all the districts above specified. It may be recognised in most of them, and often at the apex, without even a trace of its presystolic accompaniment. In a small but interesting proportion of cases the systolic mitral is associated with a true diastolic mitral, as in a patient whom I saw a day or two since in King's College Hospital (Fig. A). In this instance there is a double murmur, best heard in the neighbourhood of the apex, of which the systolic element is prolonged and blowing, not unlike a diastolic aortic murmur, while the diastolic mitral, which runs off from the second sound, is of rougher quality, resembling an untrilled "R," is uniform in power, and ends somewhat abruptly.

I now come to the consideration of that question which Dr. Dickinson has discussed with great felicity of language and undeniable dialectical skill—viz., "*How are the murmurs which accompany and indicate mitral obstruction produced?*" I must confess that to my mind the problem appears to be free from all real difficulty, and that I entirely accept the explanation formulated by Dr. Gairdner many years ago. I believe that all the different varieties of murmur of mitral origin occurring between the second and first sounds of the heart are due to rhythmical vibrations, or (if it be preferred so to express it) to fluid veins, determined by the passage of blood from the auricle through the contracted mitral orifice into the ventricle; and that the reason why the so-called presystolic murmur is more common than the murmurs arising in the earlier part of the diastolic period, and is for the most part coarser and rougher than they, is that, as physiologists teach us, the systole of the auricle immediately precedes the systole of the ventricle and the occurrence of the first sound of the heart, and causes, while it lasts, a specially forcible current from the one cavity to the other. That the earlier diastolic mitral murmurs—viz., those running off from the second sound, and those that are isolated in the mid-diastolic period—are direct, no one, so far as I know, denies, and Dr. Dickinson himself believes. But if such an explanation is regarded as sufficient for murmurs developed from or shortly after the second sound of the heart, why should it not equally apply to murmurs occurring just before, and running up to, the first sound? Surely the fact that the contraction of the auricle at that time renders the flow of blood more rapid than it was before furnishes no intelligible reason for discarding the auricular systole as the principal agent in the production of such murmurs.

The reasons in favour of the view that the presystolic murmur (which is alone in dispute) is determined by the onward flow of blood from the auricle to the ventricle are mainly as follows:—1. It accords with the physiological fact that the contraction of the auricle, to which it is attributed, immediately precedes, and runs on into, the ventricular systole, the very commencement of which is timed by the first sound of the heart, in which the presystolic murmur itself ends. 2. The murmur precedes the arterial pulse, ends with the apex beat, and occupies a time, therefore, in the cardiac cycle, which would otherwise be a time of silence, and a time which we have always been taught to regard as the close of the cardiac diastole. 3. The presystolic murmur does not differ in quality from the diastolic mitral murmurs of earlier period. It is true that the latter are for the most part feebler, but though feeble they are generally characteristically rough, and not very unfrequently they present a degree of roughness which equals or surpasses that of the presystolic murmur itself. 4. All the different kinds of mitral obstructive murmurs are equally characterised by consonantal noisiness, and consonantal want of penetrating power, and thus are always audible over a curiously restricted area. 5. They are not conveyed into the axilla or to the angle of the scapula as systolic mitral murmurs are conducted, and as they would certainly also be conducted were they due to regurgitation.

Among the arguments which are adduced on the opposite side of the question are the following:—1. The force with which the blood is driven into the ventricle by the contractions of the thin-walled auricle is insufficient to cause the roughness and loudness of sound distinctive of the murmur in question. In answer to this, it would seem sufficient to to say that equally loud and rough murmurs may be developed during the earlier part of the diastolic period, when the force of the blood current is chiefly dependent on the suction exercised by the expanding ventricle. But it is a mistake to suppose that the loudness and roughness of the presystolic murmur need much velocity of current for their production. The murmur, as I have before stated, is like a trilled "R," and is made up of coarse vibrations, which follow one another far too slowly to cause a musical note. There is no such forcible escape of air in the production of the trilled "R," as there is in whistling or simply blowing. Rather, the breath escapes in volume, but slowly, past the vibrating barrier. I do not argue that the slower the current the louder should be the characteristic murmur; but I hold that moderate rapidity is best adapted for its production, and that greater rapidity would probably convert the trill either into a musical note or into a noiseless whiff. 2. The running of the presystolic murmur into the systolic mitral murmur (when the two sounds coexist), without any discernible interval between them excepting that due to the presence of the first sound (which, in fact, unites them), is held to prove that the two murmurs must be due to a single action, and consequently to the contraction of the ventricle alone. It is argued that if the former of the two sounds is produced by the contraction of the auricle and during the flow of blood from the auricle into the ventricle, and the second is (as everyone acknowledges it is) caused by the contraction of the ventricle and the reversal of the blood current through the insufficiently protected mitral orifice, there must of necessity be a momentary interval of silence between the end of the presystolic murmur and the first sound of the heart, from which the later murmur starts; just as there is an interval of silence between each pair of respiratory acts, and a momentary pause between the end of a swing of the pendulum and the beginning of the one following, or (to take an even more apposite example), as there certainly is, between the successive elements of a to-and-fro aortic murmur. Such illustrations are valuable as helping to make clear the point of view of those who quote them; but they are of little value in determining the question at issue, unless it can be shown that their conditions are identical with, or analogous to, the conditions of the problems to be solved. I do not think that such is the case here. As I understand the action of the heart, and I believe it is the view which is generally taught by physiologists, the contractions of the auricle and ventricle are not so much an alternate contraction of these two cavities, as they are a rapid peristaltic movement beginning in the auricle and continued without pause into the contraction of the ventricle. If that be the case, even though there be a real reversal of the current between the auricle and ventricle at the moment when, on the cessation of the auricular systole, the ventricle begins to contract, no pause between the two actions is necessitated, and none need be assumed. Even if there were a pause, it might be so short that the ear would be unable to detect it. There is no audible break, so far as I know, in a prolonged, presumably continuous, note on the violin made by a competent player with a to-and-fro sweep of his bow. Nor is it difficult, I think, to utter with the lips a continuous noise determined by alternate inspirations and expirations. No doubt the inspiratory and expiratory sounds must differ from one another in quality; but that does not imply discontinuity in time. 3. It is argued that the presystolic murmur is produced in a period corresponding to what in the healthily acting heart might be termed the early silent stage of the ventricular contraction, or a brief period of contraction immediately preceding the closure of the mitral valves; that, owing to the leisurely closure of the thick and clumsy curtains when mitral obstructive disease is present, this period becomes prolonged, and that while it lasts the blood in regurgitating is a continually diminishing stream until the actual closure is effected with the snap of the first sound. I must confess that this explanation, ingenious as I admit it to be, seems to me altogether gratuitous. I am not aware that there is any sufficient anatomical or physiological basis for any such hypothesis, and it seems to me, as I have already incidentally tried to show, contradicted by the other clinical facts which are associated with the presystolic murmur. If the length of this murmur at the apex be a measure of the time during which the ventricle is contracting upon its contents before the advent of the first sound, it is thought (when obstructive aortic disease is associated with obstructive mitral disease)

Digitized by Google

to be also a presystolic aortic murmur. Is any such murmur ever heard? Again, if during all this period the blood is flowing backwards into the auricle, it must also be flowing simultaneously onwards into the arteries, and the radial and carotid pulses (or, at any rate, their commencements) should be coincident with the beginning of the presystolic murmur. But the pulse in these cases, as in all others, is simultaneous with the apex beat and the first sound of the heart. Again, how are those cases to be explained in which, as in that of my patient, the whole interval between the second and first sound is occupied by a continuous roar? Must we assume that the whole of this period, as well as the period of silence, is occupied with the ventricular systole, leaving no room whatever for the diastole? Or must we assume that the cardiac incidents become so much disarranged that the first sound, instead of ushering in the ventricular systole (as it should do), ends it, and that the deposed ventricular diastole has to fit itself to the interval between the first and second sound? I know how these questions might be answered by those who accept Dr. Barclay's views; but the obvious answer involves an admission which is practically destructive of them.

Before concluding my paper, I should like to say a word or two with regard to a murmur, or group of murmurs, which has in many respects a striking resemblance to the group of obstructive mitral murmurs. I mean the murmurs often termed hæmic, which are generally best heard about the sternal end of the cartilage of the left third rib, and which may extend into the contiguous portions of the second and third interspaces, and even be prolonged a little way down the left half of the sternum. The murmurs in question are harsh and rough, not like a trilled "R," but sharper and more scratchy (as I believe the late Dr. Sibson described them). They are so rough in quality, and their roughnesses are so distinct, that they are undoubtedly suggestive of pericardial friction, and are not unfrequently, I believe, assumed to be due to the presence of recent or old pericardial lymph beneath the area over which they are heard. It would be difficult for a tyro not to believe that they are due to organic diseases within or outside the pulmonary artery or conus arteriosus. Their main peculiarity, apart from roughness, is that they tend to occupy the whole of the systolic period. (Fig. H.) In some instances the murmur runs off from the first sound, and dies away, like a systolic aortic murmur does, during the systolic period; in some it occurs mainly, if not alone, during the latter part of the systolic period, and, gathering force in its progress, runs into the second sound, which is usually markedly accentuated; while in some, again (and one of the patients whom I have brought with me exemplifies the fact), the murmur occupies the whole of the systole, running off from the first sound, becoming comparatively feeble in the mid-systolic period, and increasing again in volume as it approaches the second sound. Whether such a murmur is ever due to disease of the pulmonic valve or pulmonary artery I cannot say. But I am quite sure, and have proved it to myself by post-mortem examination and by clinical observation, that in the great majority of cases it occurs in connexion with structurally healthy right ventricles, pulmonary arteries, and pulmonic valves, and that the murmur is therefore a so-called functional murmur. How it is caused I do not pretend to decide. That (although it largely occurs in anæmic persons) it is directly due to altered quality of the blood I do not in the least believe. I should think it is connected with some want of due relation between the quantity of blood expelled from the ventricle in a given time and the size or tension of the pulmonary artery, allowing of the development of coarse vibrations of the contents and walls of that part of the circulatory apparatus over which it is best heard. So far as I can see, the occurrence of prediastolic pulmonic murmurs in cases in which the parts concerned are structurally healthy favours the general belief that presystolic murmurs (which so much resemble them) are direct murmurs arising during the onward flow of blood. I see by THE LANCET of last Saturday that Dr. Charlewood Turner, on the assumption that such pulmonic murmurs are due to organic disease of the pulmonic valves, attributes them to regurgitation occurring at the pulmonic orifice prior to the complete closure of the pulmonic valves and the occurrence of the second sound; and quotes this supposed fact as an additional argument in favour of Dr. Barclay and his disciples' views as to the causation of the mitral presystolic murmur.

A REPORT OF CASES (SURGICAL AND MEDICAL).

BY J. HARRIS JONES, L.R.C.P. EDIN., L.F.P.S. GLASG.

(*Concluded from page 910.*)

Pyo-nephrosis; nephrotomy; cure. — Mrs. W——, aged forty-four years, was seen by me on the 11th of December last. Her health had been very indifferent for years. She complained of severe pain in the right lumbar region, which was generally accompanied by considerable uneasiness in the neck of the bladder. Micturition was frequent and painful, and for the last eighteen months she had been constantly passing "matter" with her urine. About ten years ago, after an unusual exertion, she observed blood in the urine on one occasion. She dates her present illness from that period. A year ago last September she felt a "lump" in her side, which slowly increased in size, and gradually approached towards the middle line of the abdomen. Early last summer she voided a very large amount of pus per urethram, and she thinks that some also escaped from the bowels. This had the effect of considerably diminishing the size of the tumour. Soon after, however, it grew to its former dimensions, and had remained at about its present size for the last six months. She had been under the care of several physicians, and had taken a great deal of medicine. Her disease had been variously diagnosed and treated. When I saw her she had been confined to her bed for about three months. Her complexion was very sallow, and she was greatly emaciated. Upon examination, I discovered a tumour stretching diagonally across the abdomen, commencing on the right side from beneath the floating ribs, and extending to a point two inches below the umbilicus and a little beyond the linea alba. It was deep-seated. When pressed upon, it gave an indistinct sensation of elasticity, but no fluctuation could be detected in it. There was no fulness in the right loin. The ascending colon was recognised by its resonance lying in front of the growth, but instead of following its usual upward course it had been pushed forward by the tumour to within a few inches of the middle line of the abdomen. The urine contained a large amount of pus, and was consequently albuminous. Under the microscope the slide was seen studded with pus corpuscles. The patient and her friends, having been told by previous medical attendants that surgical interference would be of no avail in this case, were much opposed to an operation, but after much persuasion on my part they reluctantly consented to an aspiration, and if the sac refilled they would permit me to cut down upon the abscess. On Dec. 27th, with the assistance of Dr. G. W. Guthrie (who a few days previously had seen the case with me), I inserted a needle at a point a little in front of the anterior extremity of the last rib, and aspirated about six ounces of very thick and foul-smelling pus. The operation gave some relief, and for a few days afterwards the urine was freer of pus and had increased in quantity. It was but a short time, however, before the sac refilled and all the old symptoms returned. On Jan. 4th it was noted that she was rapidly sinking, and that life could exist but a few days longer. Consent was given to perform nephrotomy the following morning. On the 5th the patient appeared to be weaker, and it was feared she might die under the operation. Having secured the assistance of Drs. Guthrie and Long, we decided to operate in spite of all odds.

Operation.—The patient took the ether very badly, and it was with much difficulty that the heart was kept beating until the operation was completed. She was turned on her side and the incision was made a little further from the spine than is generally recommended. It was deemed perfectly safe to do so, as the colon and peritoneum had been lifted several inches forward by the tumour, and I felt that by making it here I should likely strike the edge of the kidney and enter the sac at once. The different layers of muscles were divided upon a director to the extent of two and a half inches. A layer of adipose tissue bulged into the spinal end of the wound, and, after clearing it away, the edge of the kidney and sac was reached. A probe was inserted into it, and pus escaped. The opening was enlarged to the extent of the superficial wound, and the finger intro-

Digitized by Google

duced. About ten ounces of pus were liberated. The parts were thoroughly searched with finger and probe, but no stone could be discovered. When my finger was in the pelvis of the kidney (which was now converted into a large sac) the opening of the ureter was distinctly felt. It was patent, but the tissues surrounding it were very much indurated and thickened. The cavity was washed out with a solution of perchloride of mercury (1 in 2000), and a large drainage tube inserted.

The patient for several hours after the operation wavered between life and death, but with the aid of hypodermic injections of ammonia and whisky, and hot bottles applied to the sides and feet, reaction was finally established. She improved very rapidly after this. Vomiting, which had been a constant annoyance before, ceased, and her appetite soon became voracious. The urine voided a few hours after the operation was slightly bloody, but in a day or two it became "clearer than it had been for years." On the eleventh day it did not contain a trace of albumen or of pus. I have examined it on several occasions since, the last time about a month ago, but have never succeeded in discovering any abnormality in it. The wound was washed daily with an antiseptic solution. It has not, however, completely healed. A sinus remains, which has so far baffled every treatment. It gives very little annoyance, and the discharge from it is scanty and watery. Strangely, a polypus was seen growing into it, and I attempted its removal by torsion on two occasions, but each time it broke off and only a portion was removed. On the third attempt I succeeded in completely removing it. It measured about two inches and a half in length, and tapered at its base to a mere thread. This was accomplished about three months ago, and there has been no indication of its return. My patient, I am pleased to say, enjoys good health, and the only discomfort she experiences from the sinus is when the exuberant granulations at its mouth have to be touched with a caustic.

Rectal Tumours of peculiar growth; removal; recovery.—Mrs. H——, aged sixty-three years, had been complaining for the past two years of symptoms very closely resembling those of chronic dysentery. She felt as if the bowels constantly required to be moved, and when she went to stool she could pass nothing but a little blood and slime. The tenesmus and tormina accompanying the act were almost unbearable, and were rapidly exhausting the little strength she had. She did not remember how long it was since she had a natural fæcal passage, but it must have been at least two years ago. She had undergone much treatment for "dysentery and ulceration of the bowels," but had received no benefit, and, instead of improving, she was rapidly growing worse. Her family physician (who had been taken ill and compelled to leave for change of air) had detected several small tumours in the abdomen. They were supposed to be glandular enlargements, and were treated with an iodine ointment. They rapidly disappeared; but one, which was larger than the rest, remained. When I saw her in March last, I could distinctly feel a tumour, apparently about the size of a small orange, situated in the left iliac region, and lying closely to, and on a level with, the anterior superior spinous process of the ilium. It was slightly movable. A few days after, when making an examination with the finger of one hand inserted in the rectum and a finger of the other hand in the vagina, I distinctly felt from the latter opening a round growth lying high up between the rectum and the vaginal wall, which when pressed upon in a backward direction could be faintly touched with the finger in the rectum. The tenesmus continuing had the effect of bringing the growth a little lower. As soon as the former subsided the tumour would recede beyond reach, and could be felt occupying the position previously stated in the abdomen. The constant pain began to tell upon the patient's strength, and I decided to remove the growth as soon as it would come down within reach.

Operation.—On April 23rd, with the assistance of Drs. Mayer and Long, the patient was etherised, and although the tumour was lying high in the rectum we resolved to remove it if possible. Having first thoroughly dilated the sphincter ani with my fingers, the hand was introduced into the rectum, and the growth grasped. Traction was tried, but owing to the friability of the tumour it was not persevered with. The pedicle was felt to be immensely broad and thick, but no pulsation could be detected in it. With the assistance of Dr. Mayer, a needle containing a double ligature of whipcord was with great difficulty inserted through the pedicle, and one half of it was encircled and tied. The other ligature having become displaced, and finding that the hæmorrhage had been insignificant, we decided to leave the remaining portion untied. The growth was easily peeled off with the finger. After its removal it was found to consist of three separate tumours. The largest was about the size of a pullet's egg, the other two were much smaller. Sections of them were made and examined. Under the microscope they appeared to have the characteristics of a myxoma.

There has been no return of the growths. The tenesmus ceased immediately after the operation, and the patient's health rapidly improved. The bowels are now regular, and the fæces are naturally formed. The severe dilatation to which the sphincter was subjected did not impair it in any way.

Purpura Hæmorrhagica Syphilitica occurring in an infant four days old; death.—On April 19th of the present year Mrs. L—— was confined for the third time. Labour was short and easy; but the placenta not coming away, I was sent for to remove it. The child, a male, looked healthy and strong. Knowing that the father was syphilitic, and that the other children had died in infancy, the last one from syphilis, I requested the mother to send for me if she noticed anything wrong with the infant. On the fourth day I was sent for. The child had been bleeding slightly from the umbilicus. Having requested the nurse to divest it of all its clothing, I observed several large purple patches scattered over the chest, abdomen, and armpits. They were unmistakably purpuric. There had been some bleeding from the nose, and the nurse told me that she had observed a little blood on the napkin that morning. Small doses of mercury and chalk and a mixture of iron and cod-liver oil emulsion were prescribed for it. The child continued to grow worse. Fresh purpuric spots appeared, and the epistaxis and melæna increased in severity. The urine on a few occasions was bloody. The child died on the eleventh day.

Remarks.—I have reported this case for two reasons. Firstly, because of the extreme rarity of purpura in so young a child, and, secondly, on account of the doubt which exists in the minds of syphilographers as to the existence of a syphilitic form of this disease. I could assign no cause for purpura in this case, other than that of syphilis, and I think that I have sufficient evidence to justify the opinion that it was an expression of that dyscrasia.

Wilkes-Barre, Pennsylvania.

ON THE ACTION OF CERTAIN DRUGS ON THE CIRCULATION AND SECRETION OF THE KIDNEY.[1]

BY C. D. F. PHILLIPS, M.D., F.R.S.E.

THE following paper, which is compressed to the smallest possible space, is founded on experiments undertaken by me, in conjunction with Mr. Rose Bradford, in the Physiological Laboratory of University College, London.

The evidence at present obtainable from experimental pharmacology as to the precise mode of action of diuretics is by no means satisfactory. The question is a complicated one. Merely to observe the effects of any drug on the urinary flow and the blood pressure is a fallacious method; the important factor, which is omitted, is the effect of the drug on the *renal bloodvessels*. It does not necessarily follow that a drug has the same action on all peripheral vessels, and it is quite conceivable that it may constrict those of one area and dilate those of another. This is particularly true of the kidney vessels, where the flow of urine is not so much dependent on the general blood pressure as on the difference between the renal vessels and those of the body at large. Thus an ideal diuretic would be one that dilated the bloodvessels of the kidney, but constricted all others in the body. On account of considerations such as these, it occurred to Mr. Rose Bradford and myself that it would be well to reinvestigate the action of drugs on the kidney from a rather different standpoint to that usually adopted.

Mosso and others have investigated the peripheral circulation by enclosing a portion of the body, such as the arm or

[1] Paper read at the Ninth International Medical Congress, held at Washington.

eg, in a rigid vessel filled with fluid and communicating with a delicate registering apparatus, so that any expansion of the limb would, by causing on outflow of fluid, produce a movement of the registering apparatus, which could be recorded graphically on the blackened surface of a revolving drum. Dr. Roy of Cambridge has extended this method to other organs, such as the heart and kidney. In this method the kidney is enclosed in a metal box filled with warm oil, the box being of such construction that no oil is allowed to leak out, and at the same time the structures at the hilus of the organ (vessels, ureter, and nerves) are not injuriously pressed on. This is effected by the box or oncometer being made in two similar halves, and each half having a piece of peritoneum (specially prepared) applied to it in such a manner that the space between the membrane and wall of the oncometer can be filled with oil. The two halves of the instrument are hinged together, and the kidney placed between the corresponding membranes of opposite halves. This membrane, being very flexible, applies itself acurately to the kidney, so that, to use a simile, the kidney placed in the oncometer resembles, for instance, the heart enclosed in the pericardium full of fluid. The heart would represent the kidney, and the visceral layer of the pericardium the delicate membrane of the oncometer; the pericardial sac finding its equivalent in the oncometer, and the pericardial fluid in the oil filling the instrument. It is obvious, then, that if the oil in the oncometer be placed in communication with a recording apparatus, any expansion of the kidney can be readily detected, and recorded graphically in the usual manner. The recording instrument is called by Dr. Roy the oncograph, to distinguish it from the oncometer. Its exceeding delicacy is shown by the fact that the tracing obtained in this manner from the kidney, say of the dog, is practically identical with a simultaneous tracing of the carotid blood pressure; the slight expansions of the kidney caused by each heart beat, as well as those caused by the respiratory undulations of the blood pressure, being perfectly recorded by this instrument. If, now, in the same animal, we record simultaneously the general blood pressure, the expansion and contraction of the kidney, and the excretion of every drop of urine, we can determine the action of any given drug much more completely than before. Our method of experimentation was shortly as follows. The animal (cat or dog) having been anæsthetised with chloroform, or with chloroform and morphia, a cannula was placed in the usual manner in the carotid. The kidney was then exposed, carefully separated from surrounding structures, and placed in the oncometer, this having been previously filled with oil. A cannula was then placed in the ureter, and each drop of urine falling from it was made to break a circuit through an electromagnetic arrangement, so as to make a mark on the recording surface for each drop. Before commencing the actual experiment, the animal was curarised to prevent any movements, and artificial respiration was maintained. Finally, a cannula was placed in the external jugular for injection of the drugs experimented with. In an experiment performed in this way, the blood-pressure curve and the kidney curve remain constant for several hours. The flow of urine is also very constant in its rate in the same animal, but varies in different animals. It is important that the amount of chloroform administered should be constant. This was effected by blowing the air from the artificial respiration apparatus through a bottle containing chloroform.

We will now pass to the action of various drugs, taking first citrate of caffeine. The effects produced by half-grain doses are as follows: 1. On the *blood pressure*. The blood-pressure is first lowered, and then is raised. Both effects are of short duration and slight, especially the rise of pressure. 2. On the *heart*, there is first a diminution in the force of the beats, followed by a slowing, with beats of markedly increased force. 3. On the *kidney*, there is at first contraction lasting two or three minutes, and accompanied by diminution or even arrest of secretion. This is followed by expansion, which (after a one-grain dose) lasts sometimes over half an hour, the flow of urine being simultaneously trebled. The effects on the kidney cannot be the result of the changes in the general blood pressure; this is shown by the fact that they do not occur simultaneously. The effects on the general pressure are slight and last only a few seconds, those on the kidney being measured by minutes.

Another drug which acts in a similar way is ulexin, a new alkaloid obtained from the seeds of the common gorse (Ulex Europæus). It has the objection that in animals the diuretic action is only maintained with doses which would either kill through the respiration or produce violent convulsions. It resembles caffeine in producing first a constriction and then an expansion of the renal vessels, with diuresis. It differs from caffeine in three particulars: 1. It is more powerful. 2. Its effects are more transitory. 3. Repeated doses of caffeine rapidly injected produce contraction only of the kidney, not followed by expansion; but similar excess of ulexin causes only expansion without contraction.

Among other substances that cause expansion of the kidney we may cite dextrose, urea, acetate and chloride of sodium, and probably all the constituents of the urine.

The drugs producing constriction of the kidney are more numerous. Digitalin in doses of $\frac{1}{10}$ gr. causes contraction, which persists for as long as half an hour. It is not easy to decide whether digitalis is a true diuretic, or only exerts its effects through the heart. During the contraction of the kidney, however, the flow of urine is not diminished, as is the case with caffeine, but is generally increased. The explanation seems to lie in the effect on the general blood pressure, digitalin raising it, caffeine depressing it. Spartein, on the other hand, though it acts similarly to digitalin on the heart, general blood pressure, and renal vessels, causes a great diminution of urine; and in disease, its so-called diuretic effect is due to improvement of the general circulation. We have also made many observations with strophanthin and apocynëin; their chief action is on the heart muscle; they produce little or no effect on the peripheral vessels. Both cause a slight temporary contraction of the kidney vessels, but with no definite increase in the urinary secretion. Finally, turpentine, adonidin, and barium chloride all produce marked contraction of the kidney, without diuresis.

In summing up the results, we see that reputed diuretics more commonly produce contraction of the renal vessels than expansion. Further, that expansion is either slight, as by acetate of soda; or, if large, as by citrate of caffeine, is only produced by small and initial doses. The powerful action of ulexin on the respiratory mechanism is a great drawback to its use; one-sixth of a grain was used in our experiments, but one-twelfth of a grain would completely arrest respiration. Then, again, such drugs as produce contraction of the kidney cannot be bracketed together, since, though they all have the same effect on blood pressure, digitalin alone has an obviously diuretic effect. We further see evidence of the truth that the flow of urine is not so much dependent on blood pressure as on the rate of the flow of blood in the renal vessels. It is necessary also to remember that although such drugs as strophantin produce a great increase in the force of the cardiac beats, yet the heart is very much slowed, so that it is possible that the amount of blood sent into such an organ as the kidney in a given time may remain the same, whereas such a drug as digitalis, producing a rise of blood pressure and a contraction of the kidney vessels, may cause an increased quantity of blood to pass through those vessels, and thus it acts as a diuretic. Inasmuch as spartein has not a marked diuretic action, we must also assume that digitalin has some peripheral action on the secretory apparatus of the kidney.

Our results may be tabulated briefly as follows, in three divisions:—

A. Drugs that first *contract* and afterwards *dilate* the kidney. I shall mention two out of this class: 1. Caffeine, in small doses, induces in the stage of contraction a fall of blood pressure; in that of expansion, a slight rise. During the former, the flow of urine may be arrested; during the latter it is always increased, *such increase depending on dilatation of renal vessels.* The possible arrest of secretion during the first stage is special to caffeine, and may be induced by large or repeated doses. 2. Ulexin, one-sixth of a grain, greatly raises blood pressure during the first stage (that of contraction); in the second, expansion is much greater in degree but shorter in duration than under caffeine, and is accompanied by brief but marked increase in urinary flow: the effective dose is limited by its toxic action on respiratory centres. Practically, excess of caffeine induces only the first stage, excess of ulexin only the second.

B. Substances that dilate the kidney, but to less extent and more slowly than caffeine and ulexin, are dextrose, urea, sodium, chloride and acetate, and probably all constituents of the urine.

C. Drugs that contract the kidney without subsequent expansion:—(1) Digitalin, with increased secretion of

Digitized by Google

urine—probably resulting from general heightened blood-pressure. (2) Spartein, with diminished secretion—in health at least. (3) Strophanthin causes slight temporary contraction, with no marked increase of secretion. (4) Apocynëin, similar temporary contraction, and no definite increase of secretion. (5) Turpentine, (6) adonidin, and (7) varium chloride give similar results.

In conclusion, it seems to us that the plethysmographic method of experimentation is a valuable one for determining the exact action of drugs on the circulation, and one that deserves more attention than it has hitherto attracted.

Henrietta-street, Cavendish-square, W.

NON-TUBERCULATED LEPROSY WITH LOCAL ASPHYXIA BETWEEN THE ANÆSTHETIC PATCHES.

BY BEAVEN RAKE, M.D. LOND.,
MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM.

LEPROSY, as is well known, furnishes frequent and typical examples of the various trophic lesions so often discussed in Europe. It is, however, in connexion with the more obscure condition known as local asphyxia, or Raynaud's disease, that I venture to relate this case. It is unique in my experience of leprosy, and derives additional interest from the fact of its occurring in a fair-skinned, intelligent European.

Chevy A——, aged forty-five, born in France, was admitted to the Trinidad Leper Asylum on May 19th, 1883. He had served in the Crimea and in various other parts of the world. I examined him from time to time, and was surprised to find how little progress the disease was making. Beyond localised areas of anæsthesia in the extremities, there was no evidence of leprosy. The anæsthetic skin was at this time of exactly the same colour as the unaffected skin. He was an active man, constantly employed in making boots or in work about the asylum. On returning from Europe in September, 1886, I was, however, struck by a remarkable change which had taken place during my absence. The following are the notes then taken.

Oct. 1st, 1886: The anæsthetic patches are of the normal white colour; all the rest of the skin is of a dusky red. On pressure with the finger the congestion disappears. On drawing the nail across the skin the dark colour vanishes, then reappears, and afterwards a distinct bright-red wheal is observed in the line of the finger. He says the congestion disappears when bathing in the sea. He complains of much pain in the limbs, especially in the palms of the hands. The fingers are anæsthetic, and becoming stiff.—25th: He has been trying friction with gurjun liniment, but says the fingers are stiffer and more painful. The left median nerve was therefore stretched under chloroform. The nerve was found to be thickened. Some juice was collected from the exposed nerve on a cover glass and examined with magenta, but no bacilli were found.—29th: He says there is a sleepy feeling in the palm of the hand in place of the anæsthesia. When tested with the eyes shut, he refers the impact of a substance to one side of the point actually touched.—Nov. 12th: Now that the rain is falling, the colour of the skin between the taches has turned to a dusky reddish blue. He says the fingers feel cold, and that sometimes the skin is almost black during the rains. There is now no change whatever in colour or sensation in the parts supplied by the median nerve operated on.—Feb. 14th, 1887: He has been rubbing the arms with a 10 per cent. solution of ichthyol in olive oil. The dark colour is a little lighter, but there is no change in the anæsthesia.—March 14th: The congestion of the skin is almost gone. Has had dysentery for the last month. Complains of a cold sensation in the abdomen.—April 16th: He has been losing much bright blood from the bowel lately. Is found to have a prolapse of the rectum, with congested ulcerated surface. He was given chloroform, and the lower two inches of the rectum were drawn down and everted. The mucous membrane was cauterised linearly in the long axis of the bowel with a black-hot wire. It was then rubbed over with fuming nitric acid and tannin applied.—29th: Since the operation he has passed a good deal of blood from time to time. This has been checked by injections of nitrate of silver and of opium, and by turpentine by the mouth. The violet colour between the taches on the upper extremities has gone, leaving dusky-red patches.—May 4th: Sitting up; walked yesterday. Had diarrhœa, but no more blood. To repeat turpentine.—6th: Has passed hardly any urine since last night. About four ounces of clear urine, smelling strongly of turpentine, were drawn off by catheter. Burning sensation over bladder.—18th: Has had fever every day at noon lately, which was relieved somewhat by ammonium picrate. Urine high coloured; a trace of albumen. Œdema of hands and feet. Frequent diarrhœa, but not much blood. Looks better in face.—19th: Died at 2 P.M.

The necropsy, next day, showed an enormous liver, weighing 83 oz., and containing five distinct abscesses; the total amount of pus was estimated at from two to three pints. Weight of spleen 18 oz.; simple hypertrophy. Weight of kidneys 9 oz.; cortices somewhat thinned and granular on surface. Aorta very atheromatous. No recent hæmorrhage or ulceration was found in the rectum, the ulcers appearing to be cicatrised; but the rest of the large intestine was invaded by numerous more or less circular and sharply defined ulcers. The median nerves were thickened, but no difference was found between that which had and that which had not been stretched. The right cervical sympathetic and ganglion of the vagus were dissected out, but no change was found. Sections also showed no change under the microscope. Magenta showed numerous cells in the median nerve, staining very dark, and apparently stuffed with bacilli, also some free bacilli. Numerous bacilli, both free and in cells, were found in a scraping from the superior cervical ganglion of the sympathetic.

This case revealed a mass of morbid anatomy, hardly an organ being sound. The condition of the skin, however, is the chief point of interest. The strange feature in the case is the appearance of the congestion between the taches four years after the onset of the anæsthesia. Was this due to a fresh increase of bacilli in the mixed nerves, leading to invasion of the sympathetic fibres? But if so, why is this condition not more common, for the thickened condition of the median is common enough in leprosy, as also the discovery of bacilli in the affected nerves. I thought, therefore, that possibly a dissection of the cervical sympathetic might throw some light on the matter. No naked-eye change was found, but the microscope showed numerous bacilli in a scraping from the superior cervical ganglion. This is in contrast to results obtained in the cerebro-spinal centres; I have failed to find bacilli in brain or cord, nor has their occurrence there, I believe, been recorded. The disappearance of the congestion after prolonged hæmorrhage from the bowel was a point of interest. Whether the connexion was sympathetic or more direct I cannot say. Altogether the case struck me as presenting a remarkable resemblance to the earlier stages of Raynaud's disease, and as being sufficiently obscure and rare to place on record.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF TRACHEOTOMY.

BY J. CRAWFORD RENTON, M.D. ED,
SURGEON TO THE EYE INFIRMARY AND TO THE DISPENSARY OF THE WESTERN INFIRMARY, GLASGOW.

THE following case presents several points of interest, and is, I think, worthy of record.

J. C——, aged seventeen months, was first seen on January 22nd, 1886, complaining of symptoms of laryngitis, with absence of the typical cough. The child had been ill for six days, the mother stated, but to-day she had observed some difficulty in breathing, which caused her some alarm. Pulse 120; temperature 101°. No cervical swelling, and no exudation on the fauces or tonsils. The usual remedies were resorted to, and were continued until January 26th, when the child had a severe spasmodic attack, with obstruction to the breathing, lasting for half an hour afterwards. Tracheotomy was advised, and in this Dr. Bostock concurred. The operation, however, was delayed, as the child

Digitized by Google

seemed slightly better. Mercurial inunction was had recourse to, as we thought it possible that some specific affection of the larynx might be causing the hoarseness and spasms. On January 31st the spasms were more frequent, and there was greater difficulty of breathing. Assisted by Dr. Beatson, I opened the trachea, with immediate relief to the urgent symptoms. There was no swelling about the throat, and no special difficulty in performing the operation. One of the late Dr. Foulis's tubes was used, and the breathing was perfect until the inner tube was inserted, when a spasm immediately took place, so that it (the inner tube) was removed. The child progressed favourably for three days, when suddenly an abscess burst into the trachea and death took place. When the nurse was dressing the child after death, she noticed something sharp and prominent at the left side of the neck, an inch below and to the outer side of the wound, and drew my attention to it. On introducing my finger into the tracheal wound, I found behind it the outline of a foreign substance, not in the trachea, but evidently between it and the œsophagus. Cutting down on the external sharp point, a pin was extracted measuring two inches in length, and from its appearance it was evident that it had belonged to a brooch or safety pin. I was allowed to examine the throat, and found that an abscess existed between the trachea and gullet, which had burst into the windpipe and caused the fatal result. The larynx and trachea were quite healthy, there being no evidence of any affection of the vocal cords.

Remarks.—On explaining the cause of death to the child's mother, she stated that three months previously, while from home, a brooch was found without the pin, which had been broken, and, like many other children, our little patient often put beads, pins, &c., into her mouth, and while in the country she may have swallowed the brooch pin. It is quite possible for a pin to remain in the œsophagus for a considerable time without causing any irritation, especially if it is fixed perpendicularly. Some displacement takes place and an abscess gradually forms, pressure on the trachea causing spasm, which in the present case necessitated tracheotomy; finally the abscess burst and displaced the pin into the position in which we found it. This case illustrates the importance of bearing in mind the possibility of foreign bodies in the larynx, trachea, and œsophagus producing spasm and difficulty of breathing, even where there is no history of such being swallowed to guide us. An examination of the larynx with the laryngoscope might have aided us, but as we felt certain that we were either dealing with an inflammatory or specific affection of the windpipe, we deemed it unnecessary to give the child chloroform for that purpose.

PARALYSIS OF THE ABDUCTORS OF THE VOCAL CORDS.

BY A. LEGGE ROE, L.K.Q.C.P.I., L.R.C.S.I.,
RESIDENT SURGEON, HULL AND SCULCOATES DISPENSARY.

I READ with much interest the paper by Dr. Gordon Holmes in THE LANCET of the 22nd and 29th ult. During the last few weeks I have had under my care at the Hull and Sculcoates Dispensary two well-marked cases of this somewhat rare disease. The first was a man aged forty-five, who complained of marked inspiratory difficulty, which laryngoscopic examination proved to be caused by bilateral paralysis of the abductor muscles. Careful examination of the chest gave negative results. Unfortunately, being pressed for time, a complete history was not then obtained, and the man on being informed of the serious nature of the affection ceased to attend, and has been lost sight of.

The second case, a woman aged fifty-eight, is at present under treatment. She gives a most clear history of an attack of laryngitis twenty years ago, which was shortly followed by difficulty in breathing, most marked on exertion or when she had a cold. This difficulty has remained ever since. Laryngoscopic examination revealed complete paralysis of the abductor muscles; the vocal cords do not separate more than two millimetres on inspiration, and on forcible inspiration are almost driven together by the in-rushing air. Voice unaltered; sonorous inspiration present during quiet respiration, very loud during sleep. No enlarged glands, tumour, or other cause of pressure could be discovered.

This case is of interest on account of the clear history of the great length of time the paralysis has existed without calling for operative interference. The cold from which she was suffering when she first presented herself caused great inspiratory difficulty. This has now passed away, and the respiration is comparatively quiet.

Hull.

CASE OF SUPERFŒTATION.

BY B. G. GODFREY, L.R.C.P., M.R.C.S.

I WAS called on Aug. 17th of the present year to Mrs. H——, aged twenty-nine, to attend her in her fourth confinement. She stated she was seven and a half months gone and had been in pain all night, with considerable loss. On examination I found a three and a half months' fœtus in the vagina, which came away without difficulty. The uterus was large, rising about two inches above the umbilicus, and I could distinctly feel the movement of another fœtus. The placenta did not come away, and all pain ceased. I then left her, as there was no hæmorrhage or pain, and returning in an hour and a half found things *in statu quo*. This state of affairs continued for four days, when the pains returned, and the breech of a child was born before my arrival. I immediately removed the child, still-born, though the nurse informed me that the legs moved after their delivery. The child must have been quite seven months, as the nails were commencing to form and its weight was 4¼ lb. The placenta of the second child came away naturally, but was followed by a great deal of hæmorrhage; there was no sign of a second after-birth attached to it. Traction on the smaller cord failed to detach its placenta, so I introduced my hand into the uterus and removed it piecemeal; it was completely adherent and attached to the upper zone on the right side, measuring about 3 in. across; it was not putrid. All the bleeding immediately ceased, and my patient made an excellent recovery, without a drawback.

Balham.

DISLOCATION OF THE FIRST PHALANX OF THE INDEX-FINGER BACKWARDS.

BY E. M. HARRISON, M.R.C.S., &c.

A DISLOCATION similar to that recorded by Mr. Miller in a recent number of THE LANCET lately came under my observation, and may be worthy of a brief record.

A servant girl came to my surgery one morning, stating that in moving a heavy box her hand had slipped, the palmar surface of the proximal end of the phalanx coming into violent contact with the edge of the box. Since the accident, which happened about a quarter of an hour before I saw her, the finger had been immovable and very painful. There was no difficulty in recognising a backward dislocation of the first phalanx on to the metacarpal bone. This was easily reduced with the thumb of the left hand pressing on the displaced bone and traction on the finger with the right hand.

ST. MARY'S HOSPITAL.

TWO CASES IN WHICH THE OPERATION FOR THE RADICAL CURE OF STRANGULATED INGUINAL HERNIA WAS PERFORMED, AN ATROPHIED TESTIS BEING REMOVED AT THE SAME TIME; RECOVERY; REMARKS.

(Under the care of Mr. EDMUND OWEN.)

THE question of excision of an atrophied testis in cases where operation for strangulated hernia is performed must be left to the discretion of the operator. By the removal of the testis and cord the canal would appear to be more effectually blocked, whilst the removal of the wasted and presumably useless organ does not add materially to the severity of the operation. The best kind of suture to be

Digitized by Google

used in approximating the pillars of the ring seems doubtful, surgeons still differing as to the advisability of using wire, catgut, or silk.

CASE 1.—R. J——, a bricklayer, aged forty-four, was admitted on May 10th, 1887. For nine years he had had a right scrotal hernia, which had been strangulated two years ago, but was reduced by taxis.

The right half of the scrotum was as big as a man's fist, and very tense; the hernia had been down for fourteen hours, and all the signs of strangulation were present. Taxis having failed, herniotomy was performed. The sac being opened, about two feet of congested small intestine were exposed; the strangulation was divided at the neck of the sac. An atrophied testis was seen at the bottom of the sac. The neck of the sac and the spermatic cord having been separately tied with strong catgut, the testis and the sac were removed together. Four strong wire sutures were then deeply passed through the pillars of the external ring and the conjoined tendon, and the inguinal canal was thus obliterated. The wound was washed with a 1 per 1000 mercuric solution, a drainage tube was introduced, and the edges of the wound were brought together with wire sutures. The patient was kept on iced water for twenty-four hours, and quarter-grain doses of morphia were administered. There were no febrile symptoms. (The epididymis was subsequently examined by the microscope for seminal filaments, but with a negative result.)

On the eighth day the wound had healed throughout, the sutures were removed, and the dressings were left off. The tube had been withdrawn at the end of twenty-four hours. Thirteen days after the operation the patient was allowed to get up, there being a large plug of dense tissue filling up the inguinal canal and surrounding the external ring. On the eighteenth day, however, some pus was detected beneath the scar; this was let out and the dressings were reapplied. On the thirty-fourth day the man was discharged. But at the end of two months he was readmitted, as some suppuration continued. The four deep sutures were therefore removed; two of them were found firmly embedded in fibrous tissue; the two others were loose. The wounds at once healed by granulation, there being a mass of hard new tissue soundly filling the canal and covering the external abdominal ring. The patient was discharged cured, and was directed not to wear a truss.

CASE 2.—F. L——, aged eighteen, was admitted Aug. 16th, 1887. His right inguinal hernia had first appeared suddenly, nine years before, whilst he was pushing a truck. He was greatly collapsed, though the bowel had been down and strangulated only three hours; taxis was unavailing. The details of the herniotomy closely resembled those of the preceding case. An atrophied testis was found in the sac; the neck of the sac and the cord were ligatured separately, and the testis and the sac were removed. The external abdominal ring and the inguinal canal were obliterated by means of sutures, which included the conjoined tendon, together with parts of the aponeurosis of the external oblique, strong chromicised gut being used instead of silver.

After twenty-four hours the tube was removed. On the seventh day the dressings were left off, as the wound had healed completely. On the eighth day the patient was allowed to sit up. On the fifteenth day he was discharged. There was abundant firm material blocking up the canal and surrounding the external ring, but it was not so plentiful as in the last case, where silver sutures had been used. About three weeks after leaving the hospital the man returned to show himself, soundly healed. There was still plenty of hard material in the canal and around the ring. The deep sutures had caused no discomfort whatever, and nothing more has been heard or seen of them.

Remarks by Mr. OWEN.—Not infrequently an atrophied testis is found associated with an inguinal hernia; often such a testis is imperfectly descended, and generally it is of more than doubtful physiological value. It might be considered a good rule to remove such an imperfect gland when operating on a strangulated hernia, as by so doing the surgeon is then enabled completely to blockade the inguinal canal. The strong silver sutures which were used (as advised by Sir Wm. Stokes) demanded subsequent disinterment, whilst those of chromicised gut in the second case served their purpose perfectly. If suppuration occurs about deep sutures, the sooner the deep sutures are removed the sooner the wound will heal.

An important point is that neither of these men was allowed to wear a truss after the operation. If the work of the surgeon has been efficiently done no truss should be wanted; if a truss be applied, its pressure hurries on the absorption of the plastic material which consolidates the weak region, and its application may thus militate against the success of the operation.

I have the pleasure of saying that the second case was operated on by my house surgeon, Mr. J. J. Clarke, whilst I acted as his assistant.

BOROUGH LUNATIC ASYLUM, PORTSMOUTH.

GENERAL PARALYSIS OF THE INSANE; ONSET IN FORM OF STUPOR; APPARENT RECOVERY; RELAPSE, WITH EXPANSIVE DELIRIUM AND SPEEDY DEATH; REMARKS.

(Under the care of Mr. J. D. MORTIMER, Assist. Med. Officer.)

MR. MORTIMER expresses his obligation to Mr. W. C. Bland, medical superintendent, for permission to publish the following notes.

W. J. A——, aged forty-four, married, boiler-maker, was admitted on Dec. 19th, 1885, with the following history. He had always been a steady hard-working man; was secretary of a trade association, and had taken an active part in a recent Parliamentary election. No family history of any neurosis. On Nov. 27th he had fallen, apparently accidentally, downstairs, striking the back of his head. On Nov. 30th, he was first noticed to have a peculiar vacant look, and began to talk and act strangely, expressing an unfounded belief that his accounts were "all wrong," turning out the gas at unseasonable times, &c. He gradually passed into the state seen on admission. He was then described as a tall, gaunt man, bald-headed, with a red beard; face sallow; expression of vacant bewilderment; pupils equal, rather sluggish; tongue slightly tremulous. No definite signs of thoracic or abdominal disease, but pulse small and weak. Totters in walking; knee jerk brisk on both sides. No special rigidity or flaccidity of muscles. When questioned, he stared stupidly, giving no response, except that, when asked if he was in pain, he said his "head was bad," and passed his hand over it. He spoke slowly, but otherwise normally.

Two days after admission it was noted that the man had slept well and fed and dressed himself (but slowly). "Sits motionless and silent, replying to questions tardily and briefly. He generally answers those as to facts correctly, but for some time persisted that the present year is 1865."

Four months after admission there had been no marked change, but he was in all respects rather worse, being more dull and confused, more vacant in look and unsteady in gait, and often "wet and dirty" in habits. From this time (April, 1886) he steadily improved, at first in bodily, then in mental condition. At the end of May he was able to work in the garden, and at the end of June he was in good general health, his pulse and gait being normal and the tremor of the tongue hardly perceptible. He conversed rationally and intelligently, the only noticeable fault being a slight slowness of mental operation.

He was discharged on a month's trial, which he spent in the country, returning apparently well in all respects. He went back to work, and for two months, according to the statements of his wife and of those under whom he served, there were no signs of relapse. He seems, however, to have fretted rather unreasonably at having lost promotion by his absence, and not to have displayed much of his former activity of mind, At the end of this period he became restless and excitable, ordering expensive articles at shops and otherwise behaving insanely. After a few days he was readmitted to the asylum on Sept. 27th, 1886. He was then very boisterous and extravagant, wanting a special train to meet the Prince of Wales, proposing to make a large fortune by raffling watches, &c. His pupils were equal, gait unsteady, knee jerk brisk; tongue slightly tremulous, and there was well-marked hesitation and thickness of speech, which had only been noticed a few days. He continued in a state of acute excitement, often violent and destructive, sleeping but little; and although eating voraciously, he grew very thin and anæmic. On Dec. 1st he had a slight attack of diarrhœa, and on the evening of the 2nd suddenly passed into a state of collapse. No treatment had any effect, and he died on the morning of Dec. 3rd, 1886.

Necropsy, twenty-four hours after death.—Calvaria of normal thickness and density. Vessels of dura mater shrunken. Sinuses contained fluid blood. Arteries at base

Digitized by Google

slightly atheromatous. Convolutions flattened and closely opposed. Pia mater tough and anæmic. Decortication well marked over anterior and outer portions of frontal lobes, slightly around fissure of Rolando, hardly perceptible elsewhere. Choroid plexuses deep violet. Much fluid at base of brain and in ventricles. Ependyma granular, especially in fourth ventricle. A small gelatinous clot in right cavities of heart; fluid blood in left auricle; left ventricle contracted. The thoracic and abdominal viscera generally showed nothing noteworthy.

Remarks.—Dr. Mickle states in his work on general paralysis, that in the few cases which set in with symptoms of stupor or pseudo-dementia, "the ordinary motor and sensory signs of general paralysis are either absent at first or are masked," appearing in most cases when the extreme mental symptoms pass off. "But not always; for a marked remission, or apparent recovery, may immediately succeed the acute symptoms, some weakness of the intellectual powers remaining." This case illustrates these statements, and perhaps also the tendency of technically "recovered" general paralytics to break down on return to their ordinary course of life.

LEICESTER INFIRMARY.

CASE OF VOMITING OF GALL-STONES; DEATH; NECROPSY; COMMUNICATION BETWEEN GALL-BLADDER AND DUODENUM; REMARKS.

(Under the care of Dr. FRANK M. POPE.)

L. H——, aged forty, married, was admitted on Sept. 3rd, 1887. Her general health had been fairly good; she had never had jaundice. Two years ago she had an attack of "pleurisy and inflammation of the bowels," and a similar attack six months ago. For the last two years she has had occasional cramping pains in the abdomen. Her present illness began five weeks ago, when during the night she had violent pain in the abdomen, worse about the right hypochondrium. The pain was unrelieved by pressure, and ease was obtained only slightly by a mustard application. The next day she began to vomit, and the pain became less violent. The vomiting has continued at frequent intervals ever since. She states that she is in the fifth month of pregnancy and has had several children.

State on admission.—The patient is a stout woman with a fresh complexion. In the right hypochondrium there is marked tenderness and a sense of resistance, but no tumour. Hepatic dulness not increased. The abdomen is slightly more tender than normally, but nothing more can be made out. There was no abnormal physical signs of heart or lungs. Urine: Sp. gr. 1010; alkaline; contains no albumen or sugar. Tongue furred thinly, and rather dry. Bowels not open for two days. Temperature 98·4°; pulse 70, feeble, regular. She was ordered a bismuth mixture every four hours, and half a grain of opium in pill at the alternate four hours. Diet to be milk, lime water, and ice.

On the day after admission she was still vomiting constantly. The vomit was green at times. No other change. On Sept. 5th, two days after admission, the note was: Last night she had a considerable increase of pain, accompanied with slight convulsions and internal strabismus. She was not unconscious. She had nutrient enemata, with half an ounce of brandy in each, every four hours. Early this morning she vomited two gall-stones of about five-eighths of an inch in diameter, with six or eight facets on each, and several smaller ones. The pain continued. She was a good deal collapsed. Temperature 97°; pulse very slow and small; bowels not open. All food and medicine by the mouth were discontinued, and she had an effervescing mixture with three minims of dilute hydrocyanic acid. On the 6th she was in much the same state, and had vomited a few more small stones. On the 7th the bowels were freely opened, and the motions contained several gall-stones, one nearly three-quarters of an inch in diameter. A few more small stones were vomited. She was taking essence of beef, and a very little milk. After this she slightly improved, the vomiting almost ceased, and she began to take a little more nourishment; but on the 17th she had another convulsive attack and subsequent collapse, from which she was revived by hypodermic injections of ether. The vomiting never entirely stopped, and on the 24th diarrhœa set in, and the nutrient enemata had to be stopped. On the 25th the temperature was 100°, the highest since admission; she was rather delirious, took little food, and the diarrhœa continued. She gradually sank and died at 7.20 A.M. on the 27th, twenty-four days after admission.

Necropsy, thirty hours after death.—Body fairly well nourished. Permission was obtained only for examination of abdomen, on opening which nothing abnormal could be seen; no general peritonitis, no excess of peritoneal fluid. Uterus reaching nearly to umbilicus. On raising the liver the gall-bladder was found to be situated in a circumscribed abscess cavity, formed by the adhesion of the neighbouring organs. The gall-bladder itself was in a sloughy condition, and several ragged openings existed at its fundus; some small stones had escaped into the cavity. There was a circular opening half an inch in diameter, with well-defined edges, leading from the gall-bladder into the duodenum, at about three-quarters of an inch below the pylorus. The common and cystic ducts were patent; one or two small stones were found in the duodenum. The stomach was healthy, and there was no ulceration from the gall-bladder into it. The rest of the abdominal organs were healthy. The total number of stones vomited weighed 170 grains; those passed per rectum 103 grains.

Remarks by Mr. POPE.—This case is interesting for the following reasons. It is an example of an exceedingly rare complication—viz., vomiting of gall-stones. Cases are mentioned by Frerichs, quoting Morgagni, Hoffmann, Portal, and Bonisson. He expresses the opinion that stones may pass from the duodenum to the stomach, but does not seem to have well considered the matter. Murchison, quoting several authors and a few cases of gall-stone vomiting, says that a gall-stone of any size could not pass backwards through the pylorus,[1] and describes a necropsy in which a direct communication existed between the gall-bladder and the stomach. The case I now report proves that Murchison's view was erroneous, and it is, I believe, the only recorded case which shows that a gall-stone may enter the duodenum and then pass backwards into the stomach. The immediate cause of death I consider to be septic absorption, which the patient was too much exhausted to resist.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Mode of Fixation of the Scapula and Fracture of the Coracoid Process.—Some of the Surgery and Pathology of the Hip Joint.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S, President, in the chair.

Mr. ARBUTHNOT LANE read a paper on the Mode of Fixation of the Scapula, suggested by a Study of the Movements of that Bone in Extreme Flexion of the Shoulder Joint, and its bearing upon Fracture of the Coracoid Process. The following is an abstract of the paper:—The author showed that in extreme flexion of the shoulder joint the scapula undergoes a movement of rotation upon an axis whose general direction is obliquely inwards and forwards, and that this rotation is abruptly limited by the impact of the coracoid process upon the under surface of the clavicle. He illustrated the manner in which the frequent performance of this movement under the influence of considerable strain determines in such labourers the development of a coraco-clavicular articulation, the mechanism of which he had already described in the Guy's Hospital Reports, 1886. He then referred to the very great difficulty which is usually experienced in breaking down adhesions between the humerus or scapula, these adhesions being in most cases the result of inflammation. The difficulty arose from the inability to fix the scapula. He showed that the scapula can be firmly fixed by flexing the shoulder joint completely, the coracoid process and clavicle being held forcibly in apposition, and that when the scapula is so fixed against the clavicle the humerus can be rotated forcibly upon its own axis, and can be completely adducted and then abducted very considerably without the humerus being accompanied in its movements by the scapula. In this manner all adhesions between the two bones can be readily

[1] The exact statement of Murchison reads: "The possibility, indeed, of a large calculus passing backwards through the pylorus is very doubtful." Murchison: Diseases of the Liver, 2nd edit., p. 494.—ED. L.

Digitized by Google

broken down. He then criticised the statements made by surgical writers that the coracoid process is always broken by direct violence, and referred to two cases quoted by the author of the article on Fractures of the Upper Extremity in Holmes's System to prove the truth of the above assertion, which, he said, showed that the very reverse was true in this case, for the reason that when the shoulder joint is completely flexed it is practically impossible to fracture the coracoid process by direct violence. He also referred to the extreme inaccuracy of published statistics of the relative frequency of fractures of the several bones, and particularly of the coracoid process and acromion. He had never found a single instance of fracture of the coracoid process in the dissecting room, but he had observed that fracture of the acromion occurred more frequently than fracture of any other bone in the body.—Mr. W. ADAMS agreed with the anatomical and physiological conclusions of the author, but he could not concur with the surgical conclusions, for in an ankylosed joint it would not be possible for the joint to be flexed. The difficulty of fixing the scapula was not great. He had never found any difficulty himself in fixing the joint firmly. There often appeared to be plenty of movement, but this was of the scapula, and not really in the joint. In a few difficult cases the ankylosis could not be broken down, and he should recommend that such cases be left alone.—Mr. CLEMENT LUCAS said it was new to him that the coracoid process could be fractured in the way Mr. Lane had described, and the explanation was very easy to understand. He agreed that fracture of the acromion process was more frequent than was commonly supposed. Attempts at flexion of the shoulder would inevitably bring the coracoid process into contact with the clavicle, and so afford the necessary *point d'appui*.—Mr. HOWARD MARSH thought the explanation of fracture of the coracoid as likely to be the true one. He considered that the difficulties of fixing the shoulder joint were not so great as the author had inferred. In breaking down adhesions the use of anæsthetics was most desirable. If the joint be really fixed as determined under anæsthesia, he should advise that the case be left alone, for any temporary improvement was most likely to be followed by increased ankylosis and increase of the joint disease. The acromion may be apparently detached by the chronic rheumatic joint disease.—Mr. LANE, in reply, considered that the changes in the acromion were more frequently due to injury than to a rheumatic process.

Mr. ARBUTHNOT LANE also contributed a paper on an undescribed method by which the Superjacent Weight of the Body is transmitted in a United or Ununited Fracture of the Neck of the Femur through an acquired Ilio-femoral Articulation, and the bearing of the principle involved upon the Surgery of the Hip Joint. The following is an abstract:—In the examination of 320 bodies the author of the paper had found several instances of fracture of the neck of the femur, of which three were ununited and the remainder united. In three out of the small number of these fractures observed, he found that a large proportion of the superjacent weight of the trunk was transmitted to the femur through a new joint which had formed between a strong, dense mass of bone, which projected upwards and inwards from the anterior inter-trochanteric line and the neighbouring portion of the femur and the ilium, immediately beneath its anterior inferior spinous process. The only attribute which was common to these three cases was a very considerable displacement of the head of the femur downwards, which so altered the direction of its articular surface as to render it more or less useless for its original purpose. The most interesting of the three cases was an ununited fracture of the neck of the femur, for in it the whole or almost the whole of the superjacent weight of the body was transmitted through the ilio-femoral articulation which had developed between the callus projecting from the front of the neck of the femur and the anterior inferior spine. He thought that the mechanical principle illustrated by these three specimens, and especially by the ununited fracture, might be applied very happily to the surgery of the hip joint. He referred to the very unsatisfactory results of excision of the hip joint, and showed that, besides the shortening of the limb, the extreme insecurity of the joint resulting from the operation was the cause of its practical failure. If the upper extremity of the femur could be displaced inwards and could be connected to the innominate bone so as to form a new joint similar or identical in character with that which had developed in the three cases of fracture described in this paper, a very useful limb would be obtained, and one that would readily transmit the weight of the body without the assistance of any support, and permit of compensation of the shortening. The difficulties which would be experienced in fixing and retaining the femur in position might in some cases be very great, but not greater than our present facilities of operative treatment would enable us to meet. He also appended to the paper diagrams with short descriptions illustrating the conditions which are usually presented by united and ununited fractures of the femur.—Mr. G. D. POLLOCK asked whether the united fractures of the femur were impacted in some cases or in all.—Mr. A. E. BARKER spoke of excision of the hip joint, and thought that in early cases, where extensive destruction had not taken place, good results might be expected and obtained. He had had cases in which excision was very successful. The incision made by Mr. MacEwen did not divide the capsular muscles at all, nor were any nerves or vessels divided. With this method very satisfactory results were obtained, and the head of the femur rested on the ilium, in the position indicated by Mr. Lane as so favourable after fracture. He thought that Mr. Lane's suggestion would prove a valuable one.—Mr. PICKERING PICK referred to the outgrowth of the buttress of bone from the fractured femur as affording a support through which the weight of the body could be transmitted. Nevertheless, as in a case mentioned, a fracture united by thick fibrous capsule could form an efficient support for the weight of the body.—Mr. WARRINGTON HAWARD considered that in excision of the hip joint there was an essential difference from the conditions that obtained in Mr. Lane's specimen, for in a fracture the head of the bone remained in the acetabulum, whereas in disease of the joint the head of the femur was often dislocated and even removed. In cases of successful excision, in spite of the great shortening, good union and power might result.—Mr. HOWARD MARSH agreed that the operation of excision of the joint was very different now to what it formerly was. Absolutely unjustifiable was it to turn the head of the femur out of a large wound and saw off a large portion of the bone. He usually performed the operation now by an incision through the muscles on the back of the joint, and sawing off merely the head of the bone. The anterior incision might be suitable for the procedure suggested by Mr. Lane, and there ought to be but little difficulty in forming a joint between the head and the ilium.—Mr. BARWELL asked in what proportion of cases the buttresses of bone were found on the femur.—Mr. LANE, in reply, said that in most of the cases the united fractures were impacted; he could not state from memory the proportion of cases with buttresses.

MEDICAL SOCIETY OF LONDON.

Acute Glossitis in a Child.—The Presystolic Murmur.

A MEETING of this Society was held on Monday, Nov. 7th, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Mr. MARMADUKE SHEILD read notes of a case of Acute Glossitis in a child, aged six years, complicated by trismus. On its admission into Charing-cross Hospital on the 7th of September, it was noted that the tongue protruded from the mouth, and was enormously swollen. The jaws had closed upon it, and the teeth had ulcerated deeply into the organ, which seemed on the verge of sloughing. The child was quite unable to swallow, and there seemed danger of death from dyspnœa or starvation. The mother stated that the symptoms had come on quite suddenly after an attack of "quinsy." Under chloroform the jaws were opened with a gag, and the tongue freely incised. Free hæmorrhage occurred, and the tongue was rapidly reduced in size. It, however, remained hanging out of the mouth in a paralysed state for upwards of fourteen days. The tetanic contraction of the jaws was marked, and was overcome by the constant wearing of a gag. This was attributed to reflex irritation through the lingual branch of the fifth nerve, and the paralysis of the tongue to a combination of diffuse inflammation of its muscular substance with want of effort to retract it on the part of the child. Ultimately the case recovered perfectly. The efficacy of incisions in acute glossitis was exemplified and dwelt upon, and importance was attached to the possibility of error in the diagnosis of a deeply seated abscess of the tongue simulating glossitis. The best and safest manner of incising the different parts of the tongue was briefly touched upon.—Mr. JAMES BLACK pointed out the danger the lingual artery ran of being wounded in incising some cases of glossitis.—Dr. SIDNEY

Digitized by Google

PHILLIPS quoted cases which showed that glossitis and post-pharyngeal abscess followed exposure to foul emanations.—Dr. ANGEL MONEY maintained that the motor portion of the fifth, if not weaker than other nerves, responded much more readily to irritation.

Dr. BRISTOWE read a paper on the Presystolic Murmur, a full report of which will be found in another part of our present issue.—Dr. DICKINSON was glad to find that Dr. Bristowe recognised the murmur described by Hope. He thought it very nearly resembled the aortic diastolic bruit, from which, however, it might be diagnosed by change of posture, the mitral being heard best with the patient lying down, the aortic when standing up. The so-called presystolic bruit was accompanied by a thrill and an impulse which he maintained was due to ventricular systole. In the usual explanation the systole was represented merely by a "snap" at the end of the bruit, whereas he held that the rolling murmur ending with a snap all occurred during ventricular contraction. He explained the "mixed murmurs" (combined presystolic and systolic) by supposing a primary regurgitation through the stiffened valve segments, followed by imperfect closure with continued reflux. He could not conceive how the blood could flow in one direction and then the current should be suddenly reversed without a corresponding break or pause in the murmur.—Dr. SANSOM regarded the murmur as undoubtedly presystolic, though he differed from Dr. Gairdner as to its mode of production. He did not think it was coincident with auricular systole; it often occurred immediately after the second sound. The cause of the reflux of blood into the ventricle was the tension in the left auricle and pulmonary veins caused by the forcible action of the right heart. The snap was caused by the coming together of the flaps of the tricuspid valve. Cardiographic tracings failed to show a proportionately larger systole in mitral stenosis, which according to Dr. Dickinson's hypothesis ought to be the case.—Dr. BURNEY YEO had observed the auricular contractions in a phthisical patient, with retracted left lung; and the harsh presystolic murmur was exactly synchronous with them. There was a distinct interval between the beginning of the murmur and the carotid pulse.—Dr. BROADBENT knew of cases in which there was perfect continuity between the mitral diastolic and the presystolic murmur. He had seen one murmur grow out of the other: the presystolic from being short and running up to the first sound had been, so to speak, prolonged backwards till it began with the reduplicated second sound, and eventually it might even develop into a mitral diastolic only. Dr. Dickinson had said that the snap at one time ended the systole, and at another occurred in the middle of it. With this he could not agree. He declined to accept Dr. Sansom's theory of the causation of the snap because the right ventricle was in the same condition in mitral regurgitation, but then no snap was heard.—Sir DYCE DUCKWORTH said that if the murmur were really systolic it ought to be conveyed to the lower angle of the scapula.—Dr. KINGSTON FOWLER showed a boy of eighteen with double mitral murmur and tricuspid regurgitation. The snap was present despite the tricuspid incompetency. That stenosed mitral valves were in many cases capable of closure was proved by their "facetted" appearance post mortem.—Dr. STEPHEN MACKENZIE had seen a case with well-marked presystolic bruit, in which at the necropsy the flaps presented a roughened auricular surface, but were competent. He referred to Dr. Hilton Fagge's objection: that, if these cases were really due to incompetence, dilatation of the left ventricle should follow.—Dr. BRISTOWE, in reply, confirmed Dr. Broadbent's statement, that the right ventricle was dilated and hypertrophied in aortic regurgitation.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Nov. 2nd, G. E. Herman, M.B., Vice-President, in the chair.

Mr. BLUETT showed a Hydrocephalic Fœtus. The circumference of the head was twenty-seven inches and a quarter.

Dr. W. S. GRIFFITH exhibited a specimen of Hæmatometra and Hæmatosalpinx, in which a clot was seen extending from the body of the uterus through the Fallopian tubes, and projecting a couple of inches from the fimbriated extremity of one of them. Also a case of Pyometra, which illustrated occlusion of the cervix by pressure of a fibroid. Both these specimens were from St. Bartholomew's Hospital museum.

The PRESIDENT gave notice that a special meeting of the Society would be held on Nov. 23rd, commencing at 8 P.M., for the discussion of the subject of Extra-uterine Fœtation.

Vaginal Tumour.—Mr. GEORGE LOWE described a case in which, during a difficult and painful menstrual period of a girl aged fourteen, a painless tumour the size of a pheasant's egg formed in the left vaginal wall. This proved to be connected with a large tumour filling the pelvis and extending up to the umbilicus. There were no symptoms of constitutional disturbance. On vaginal exploration no cervix could be found, but a small depression high up posteriorly admitted a catheter for two inches. On puncture of the vaginal tumour a dark treacle-like inodorous fluid escaped. The discharge ceased. All swelling disappeared, and the patient recovered.—Mr. HERMAN thought the case was extremely like one of unilateral hæmatocolpos—i.e., double uterus and vagina, one vagina being imperforate, and the secretion of the corresponding uterus accumulating in it, while the patient menstruated through the other. Owing to the relations and characters of the parts being altered by distension, diagnosis was difficult in these cases.

Hydrocephalus as a Complication of Labour.—Dr. J. W. SWAYNE, after pointing out the rarity and dangerous nature of this complication, gave the particulars of seven cases occurring in his own practice, in three of which delivery took place spontaneously, and four required the assistance of art. In one of the former the mother died apparently from rupture of the uterus. This accident proved fatal in rather more than a fifth of the cases collected by Dr. Keith, the cause being the great stretching of the lower segment of the uterus, and the difficulty thus occasioned to the process of retraction over the head. Dr. Swayne laid great stress on an early diagnosis of this complication, and on the extreme danger of an expectant treatment, and pointed out the great importance of reducing the size of the child's head by puncture as soon as a correct diagnosis had been formed. He related cases showing the disastrous results which have arisen from delay or from attempted delivery with the forceps, owing to mistaken desire to save the life of the child.—Dr. GERVIS wished to emphasise the importance of the method of examination by inserting the hand into the vagina so as to make sure of the presence of hydrocephalus before proceeding to operate. He had met with cases of severe injury to the vagina from the forcible delivery of hydrocephalic heads, the condition not having been recognised.—Dr. BRAXTON HICKS advocated the introduction of the whole hand into the vagina for the sake of diagnosis, not only in cases of hydrocephalus, but in all cases of ambiguity, so as to see exactly the want of relation between the head and brim.—Dr. GALABIN mentioned a case which he had lately seen. The diagnosis was difficult, owing to the slight development of the cranial bones and a comparative absence of hair on the scalp. The bimanual method, with the introduction of the whole hand into the vagina, easily revealed the large size of the head. In moderate degrees of hydrocephalus in which the bones were highly developed and the sutures widened, he had found the nature of the case revealed by the blades of the forceps being widely apart when applied and easily slipping off.—Dr. PLAYFAIR said that, while he fully endorsed all that had been said as to the importance of the subject of the paper, he must take exception to the statement that it had been insufficiently treated in modern text-books. In his own work it had been fully considered, and he had pointed out the precise dangers and advocated the same rules of treatment as the author of the paper. Suspicions of intra-uterine hydrocephalus might be aroused by the peculiarly violent, almost tetanic, pains which result from the vain efforts of the uterus to make the presenting head engage the pelvis. When from the experience of former labours or actual measurement the dimensions of the pelvis are known to be normal, and the head refuses to enter the brim in spite of violent pains, the patient should be thoroughly anæsthetised and a complete exploration made with the hand in the vagina. This would certainly lead to a recognition of the difficulty, and possibly to the prevention of disaster by early puncture of the head.—Dr. BOXALL thought that in certain cases podalic version was advisable after evacuation of the fluid, though in the majority of cases it was unnecessary. In cases like that which Mr. Bluett had shown, the head was enormously dis-

Digitized by Google

tended, and the bones at the vault widely separated. If the base of the skull is brought down first, the bones of the vertex will fold together like a parachute.—Mr. JOHN PHILLIPS had met with two cases of hydrocephalus, one presented by the head, the other by the breech. The former was complicated by hydramnios. The diagnosis was easy after rupture of the membranes, and perforation was followed by an easy labour. He found that 7·5 per cent. of the total cases of hydrocephalus were complicated by hydramnios. In difficult cases, when the breech presents, he thought that the plan recommended by Tarnier, to cut into the spinal column as near the neck as possible and draw off the fluid by means of a catheter, was a good one.—Dr. GRIFFTHS stated that it would conduce to the certain determination of the cause of frequent presentation of the breech in cases of hydrocephalus if those who met with them would take the specific gravity of the hydrocephalic fluid. The specific gravity of the fœtus was stated to be 1055, and of the liquor amnii 1010 to 1015, while that of the fluid which was drawn from the head of the fœtus shown by Mr. Bluett was 1010. This difference would amply account for the floating of the head to the top of the amniotic fluid, especially early, when the fœtus is mobile in the uterus. If the disease attacked the head when it was less movable in the uterus, the head, naturally dependent, might remain so.—Mr. HERMAN spoke of the value of external palpation. By this means he thought it was easy to identify the head, and roughly judge of its size. A German writer, Brühl, had directed attention to what he called "Eindruckbarkeit" of the fœtal head—i.e., the extent to which it could be pressed down into the pelvis with the hands, and he (Mr. Herman) believed this measure was of service in forming a prognosis as to the ease or difficulty of labour. If applied in cases such as those under discussion the presence of a condition entailing difficult or impossible delivery would be at once recognised.

A Case of Hæmatometra associated with a degenerating Fibro-myoma, treated by Supra-vaginal Hysterectomy, was related by Mr. W. A. MEREDITH. The patient, aged forty-six, had been subject to a large abdominal tumour for many years. In April, 1883, the patient, who had up to that date suffered from severe menorrhagia, was seized with pleurisy, and was confined to bed for eight weeks. Menstruation ceased from that date. She suffered from abdominal tenderness and severe attacks of spasmodic pain in the tumour, till she was admitted into the Samaritan Hospital in December, 1886. The abdomen was then occupied by an enormous semi-solid growth, which was diagnosed as a uterine fibro-cyst. The vaginal portion of the cervix uteri was soft and unenlarged; its canal was occluded. The tumour, with both ovaries and tubes, was removed by supra-vaginal hysterectomy on Dec. 17th, 1886, and the patient returned home quite well six weeks later. The tumour consisted of an enormously distended uterus, with a degenerating fibroid in its anterior wall. A cavity in this growth communicated by a large oval aperture with the uterine cavity, both were filled with altered blood. The posterior wall of the uterus was greatly hypertrophied. The entire mass weighed 15 lb., and must originally have contained at least 5 lb. of blood. The complete and persistent retention arose from some cause effecting sudden occlusion of the cervical canal, probably inflammatory in its origin, and rendered permanent by partial rotation of the elongated uterine cervix during the patient's confinement in bed in 1883. The specimen demonstrates a somewhat rare incident in the life history of uterine tumours.—Dr. GALABIN thought that one of the points of interest in Mr. Meredith's case was the bearing of such on the question of uterine distension with either blood, pus, or mucus without absolute obliteration of the cervical canal. The rule was that in actual stenosis of the canal the uterus became hypertrophied to overcome the obstruction, and was not dilated. He had met with exceptions to this rule. In one instance pyometra in an old woman was the result of retroflexion, and was cured by emptying frequently by digital pressure.—Dr. GERVIS had seen many cases of dysmenorrhœa in cases of fibroid uterus connected with more or less stenosis of the cervix, but no case of actual atresia. In a case of large interstitial fibroid which he removed by supra-vaginal hysterectomy last year, the interior of the tumour was found to be in a state of necrosis, and he would like to know if Mr. Meredith had often found this condition in fibroids, and whether there were any symptoms indicative of its occurrence. In Dr. Gervis's case there had been none.—Mr. HERMAN said that we ought not to base conclusions as to the effect of obstruction to the exit of fluid from the uterus on inferences drawn from cases like the present one. The question as to the effect of flexion was one of fact to be settled by observation. Some said that dilatation of the uterus was the result, others said there was hypertrophy, but no specimens existed that showed either dilatation or hypertrophy, cases in which the uterus was fixed or which had undergone senile atrophy being excepted.—Dr. HORROCKS thought the case threw light on some cases of fibro-myomata in which, years after the climacteric, uterine hæmorrhages occurred. He suggested that the hæmatometra might be due to breaking down of the tumour which opened into the uterine cavity.—Mr. MEREDITH replied.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on Oct. 19th, Mr. Lawson Tait, F.R.C.S., in the chair.

Odontoma.—Mr. JORDAN LLOYD exhibited a rare specimen of odontoma, removed from the upper jaw of a man nineteen years of age. It measured 1¼ in. long, 1⅛ in. across, and 1 in. deep, and weighed 247 grains. The specimen is probably unique, as no such case can be found previously recorded. The tumour had been diagnosed "necrosis" prior to removal. On section it showed most characteristically the arrangements in irregular lamellæ of dentine and other dental tissues. The mass was lifted out of its bed with an elevator. The tumour occupied the site of the second and third upper right molars.

Rodent Ulcer.—Mr. EALES showed a man, aged seventy-three, on whom he had operated, removing the upper and lower eyelids, eyeball, and orbital contents on the left side, for rodent ulcer of eight years' duration, which had involved the lids and commissures, together with the conjunctiva and cornea of the left eye, freely. The specimen was also shown, together with microscopic sections of the same, which exhibited the characteristics of rodent ulcer.

Raynaud's Disease.—Dr. SUCKLING showed a strumous-looking girl, aged twelve, who was suffering from symmetrical gangrêne of the fingers and toes. When two years old she was bitten by a rabbit on the right forefinger, and three months after this the fingers began to be blistered, and since that time she has never been free for a month, always having a sore finger or toe. She suffers from paroxysmal attacks of inflammation in the fingers, accompanied with severe pain. The terminal phalanges with the distal half of the middle phalanges are lost in the fore, ring, and little fingers of both hands, the fingers being swollen, red, and ulcerated at their extremities. The thumb is inflamed and the terminal phalanx is necrosed. There is no anæsthesia and no pain. The skin of the legs is bluish and thin, and ulcerated in several places, the slightest injury causing an intractable ulcer. The terminal phalanx of each little toe has been necrosed. The knee-jerk is present; the plantar reflex lost. The condition of the extremities is always worse in cold weather. There is no history of struma in the family, but the girl herself is weakly and ill-nourished.

Ulcerative Endocarditis, with Congenital Malformation of the Heart.—Dr. SUCKLING also showed the heart of a girl, aged sixteen, in whom during life he had diagnosed ulcerative endocarditis. She was admitted into the workhouse infirmary seven weeks previously to her death, and on admission was found to be very anæmic and thin, with pyrexia of a markedly remittent nature, reaching 102° to 104°F. at night, and falling to normal in the morning, with profuse sweats. A loud systolic bruit was present over the pulmonary area, and the spleen was slightly enlarged. At the necropsy stenosis of the pulmonary orifice was found, with an incomplete ventricular septum. The left ventricle was dilated, and extensive ulceration was present at the apex, the wall being very thin in this situation. The right ventricle was hypertrophied; infarctions were present in the kidneys, and the spleen was large and very soft. The presence in this case of the pulmonary systolic bruits, though not due to ulcerative endocarditis, enabled this diagnosis to be made, for without the murmur this would have been very difficult, if not impossible.

Plum-stone impacted in Bronchus.—Dr. SIMON showed a plum-stone that had been impacted in the right bronchus of a boy aged six. On opening the trachea the stone was at once coughed out.

Suppurating Ovarian Tumour.—Mr. LAWSON TAIT showed a suppurating ovarian tumour that he had recently successfully removed.

Ovarian Cysts.—Dr. MALINS showed two pedunculated

Digitized by Google

ovarian cysts that he had successfully removed from a patient aged fifty-six.

Dr. MALINS read a paper on Varicose Veins in the Broad Ligament.

The following office-bearers have been elected for the ensuing session:—President: Mr. Ross Jordan. Ex-President: Mr. Lloyd Owen. Treasurer: Mr. Garner. Members of Council: Dr. Savage, Dr. Simon, Mr. Eales, Mr. Ker, Mr. Chavasse, Mr. Priestley Smith, Mr. Wm. Thomas, Mr. A. Clay, Mr. Bennett May, Mr. Jordan Lloyd, Mr. Messiter, and Mr. Harmar. Secretaries: Dr. Suckling and Mr. Haslam.

Reviews and Notices of Books.

A Course of Elementary Practical Histology. By WILLIAM FEARNLEY. London: Macmillan and Co. 1887.

THIS book, which forms one of the excellent series of manuals for students, differs from other text-books of practical histology in many respects. It gives a complete list of the necessary apparatus, a new classification of the structures required, and much fuller detail in the various methods of preparation and mounting than is to be found elsewhere. Every process laid down in the work has been personally tested, and the course is a most thorough and complete one, and can be carried out even without the aid of a teacher, although of course not so satisfactorily and readily as if he were present. Mr. Fearnley begins at the beginning by describing what kind of a room should be chosen for a private histological laboratory, and then urges the necessity of an index of its drawers and shelves, and a diary for the details of the daily work. A good description of the microscope and of the necessary apparatus for measuring, drawing, and photographing objects then follows; and the next chapter is devoted to reagents and minor operations, such as cleaning cover-slips and slides, ringing slides, cell-making, &c. Teasing; irrigating; applying gases, vapours, and heat; injecting; dissecting; hardening and softening; embedding; section-cutting; staining; dehydrating and clearing; and mounting, follow in due order, and are most methodically and minutely described. The amount of detailed description given by the author can only be appreciated by those conversant with the book and the processes referred to. A list of the materials to be collected, and of the animals from which they can be most readily obtained, and how they should be prepared, completes the first part of the book, and to this part no words of commendation can be too strongly applied. The second part also, so far as concerns the arrangement for filling in the particulars respecting any preparation, is suitable enough; but the paragraphs relating to the definition of terms are quite out of place, and unnecessarily increase the size of the book. Writing out definitions from Quain, Klein, Schäfer, and Purser is a tedious task; it has nothing whatever to do with practical histology, and the book would be the better for the omission of the space alloted page after page to this defining of terms. Considering that Mr. Fearnley is engaged in general medical practice, it is certainly most creditable to him that he should have found time to work out the various processes and methods, and to describe them so admirably and with such praiseworthy detail. In another edition we would suggest that if a reference to pages as well as to paragraphs were given, it would be a further improvement.

A Treatise on the Animal Alkaloids: or the Ptomaines and Leucomaines Chemically, Physiologically, and Pathologically considered in relation to Scientific Medicine. By A. M. BROWN, M.D. With an Introduction by Professor ARMAND GAUTIER. Pp. 182. London: Baillière, Tindall, and Cox. 1887.

THIS is a very unequal book. The avowed intention of the author is to submit to the scientific student in England an introduction to the study of the animal alkaloids, and it is frankly admitted that the task would have been impossible without the encouragement and aid of continental workers in this department. From the introduction by M. Armand Gautier we realise the magnitude of the task undertaken — viz., "to give a stimulus to investigations new and fruitful in the elucidation of a question the most essentially humane — the cause and mechanism of life, health, and disease." The existence of ptomaines and leucomaines, and their deleterious actions, have only been brought into prominence within recent years, and it may still be doubted whether their composition and their effects have been sufficiently worked out to lead to any very practical result beyond establishing a word of warning for medico-legal experts engaged in investigating cases of supposed criminal poisoning. Some of the chemical terms appear in a form which may send scientific investigators to the original text for information. As examples, it may be sufficient to point to the frequent recurrence of "sulphurated" and "phosphorated hydrogen," "anhydrid carbonic," and "alcohol absolute." The work is divided into three sections, dealing respectively with the cadaveric alkaloids or ptomaines, the vital alkaloids or leucomaines, and the relation of the vital or physiological alkaloids, the leucomaines, to scientific medicine. The first two sections, although they give numerous classifications and definitions, are far from satisfying. Oversights occur in the revision of the proofs; for instance, on page 40, in consecutive lines we find "Schmiedelberg" and "Schmiedberg." In the third section, however, a notable improvement occurs, both in the correctness of technical terms and in smoothness of diction, and here we glean the author's own views, which are certainly of a controversial character. Stated briefly, they assert a belief in the revival of the doctrine of "humoralism" as the basis of rational medicine. "What M. Gautier has been showing, and shows so admirably, is simply that the school of the past and the school of the future will be found to mutually support each other, and further, that humoralism, if you will, so far from being vanquished, has been only stolidly refurbishing its arms and reinspecting its resources; whilst pangermism has been exhausting its energies in sensational demonstrations of bacterial surprises and bacillar blunderings." The pages in which these views are elaborated are full of interest, although we feel disposed to take leave of the book with the author's concluding words: "Let us wait for a little, and we shall see more."

OUR LIBRARY TABLE.

Middlesex Hospital Reports.—The annual report of the cases treated in this hospital for the year 1885 presents the general features which have distinguished its predecessors, but a few changes have been made with the intention of diminishing its size and cost of production. The general table of diseases has been prepared as in previous years, but with this exception all tabular matter has been excluded. Dr. Pasteur, who is responsible for the report of the medical department, gives a general synopsis of the cases of enteric fever, a summary of each case of malignant disease treated in the medical wards for the year, and a detailed account of some instructive cases under the heading "Selected Cases of Unusual Interest." In the report of the surgical department Mr. Roger Williams adds to the number of cases of cancer which have been fully analysed from 1882 (making over 800), and his general report is exhaustive and complete. The third part of the volume is occupied by the pathological report of Dr. Kingston Fowler, and contains a brief record of 283 post-mortem examinations of medical and surgical cases. These records are not merely of interest in themselves, but are important for future reference. It would be a good thing if our metropolitan hospital reports were

Digitized by Google

more available for reference and the plan adopted more uniform.

The Quarterly Journal of Microscopical Science. Edited by Professors RAY LANKESTER, THISELTON DYER, E. KLEIN, H. MOSELEY, and ADAM SEDGWICK. New Series, No. 109, Vol. XXVIII., Part 1. London: J. and A. Churchill.—This part contains the following memoirs:—1. The Anatomy of the Madreporaria, Part 3, by G. H. Fowler, with Plates 1 and 2. 2. On the Anatomy of Mussa and Euphyllia, and on the Morphology of the Madreporian Skeleton, by H. C. Bourne, with Plates 3 and 4. 3. On the Intra-ovarian Egg of some Osseous Fishes, by Robert Scharff, with Plate 5. 4. Observations on the Structure and Distribution of Striped and Unstriped Muscle in the Animal Kingdom, and a Theory of Muscular Contraction, by C. F. Marshall, with Plate 6. 5. On the Fate of the Muscle-plate, and the Development of the Spinal Nerves and Limb Plexuses in Birds and Mammals, by A. M. Paterson, with Plates 7 and 8. 6. Note on the Ciliated Pit of Ascidians and its relation to the Nerve Ganglion, and the so-called Hypo-physial Gland, and an account of the Anatomy of Cynthia Rustica (?), by L. Sheldon, with Plates 9 and 10. 7. The Tongue and Gustatory Organs of Mephitis Mephitica, by Frederic Tuckerman, with Plate 11. 8. On the Quadrate in Mammalia, by Dr. G. Baur. 9. On the Hæmoglobin Crystals of Rodent's Blood, by W. D. Halliburton. 10. An Easy Method of obtaining Methæmoglobin Crystals for Microscopic Examination, by W. D. Halliburton.

The Journal of Physiology. Edited by MICHAEL FOSTER. Vol. VIII., Nos. 3 and 4. August, 1887. Cambridge: Cambridge Scientific Instruments Company's Works.—The following contributions are contained in this part. 1. Phillips and Bradford on the Action of certain Drugs on the Circulation and Secretion of the Kidney; Plates 4 and 5. 2. W. D. Halliburton on Muscle Plasma. 3. H. Sewall: Experiments on the Preventive Inoculation of Rattlesnake Venom. 4. A. Haig: Variations in the Excretion of Uric Acid produced by administration of Acids and Alkalies; Plate 6, Figs. 1 to 3. 5. I. Ott and C. Collmar: Pyrexial agents—Albumen, Peptone, and Neurin; Plate 6, Figs. 4 and 5.

A Manual of Physiology. By GERALD YEO, M.D., Professor of Physiology in King's College. Second Edition. Pp. 668. London: J. and A. Churchill. 1887.—We are glad to see a second edition of this excellent manual. Professor Yeo is engaged in teaching, and therefore well knows what is required by the student. The work contains a considerable amount of histology, and is illustrated by many woodcuts. The purely physiological part is thoroughly worked up to the knowledge of the present day.

Conversation Lessons on Prompt Aid to the Injured. By HENRY WEBB. With 47 Illustrations. Pp. 122. Bury: W. S. Barlow. 1887.—*First Aid to the Injured: the Ambulance Pupil.* By a PUPIL of the St. John Ambulance Association. Pp. 46. London: Crosby Lockwood and Co. 1887.—We are by no means sure that the form of question and answer adopted in the first-named of these books is the best adapted for imparting instruction. It would appear, however, that the men attending the ambulance lectures delivered at Bury by Mr. Webb represented to him that they would understand and remember them better if the text-books were arranged in that form, and especially in view of the examination which followed. In compliance with the wish thus expressed Mr. Webb prepared the present handbook, which appears to have been carefully compiled, and will doubtless prove useful not only to the persons for whose instruction it was intended, but also to those on whom the examination of ambulance classes may devolve. The book has the advantage of a copious index. "The Ambulance Pupil" is another addition to ambulance literature. The instructions are given plainly and concisely. The book is of a portable size and form, and seems well adapted to the use of the class for whom it is intended. Like the one just noticed, it has a good index. In the directions for the treatment of "alcoholic poisoning" (drunkenness) we miss a very necessary caution against placing the patient on his back—a position which, if he became sick, would be very liable to give rise to suffocation.

Wintering Abroad. By Dr. ALFRED DRYSDALE. Second Edition. Pp. 63. London: Virtue and Co. 1887.—The object of this work appears to be to recommend the Riviera in preference to all other places as a winter residence for invalids, and Mentone as the best of all the winter stations. We cannot say that it adds anything to our knowledge on these subjects. The very brief notices of "the different winter stations for the benefit of those who are wholly ignorant of the subject" can scarcely be of much use in aiding them to form an opinion as to the most suitable winter residence.

Health Maps. A complete series of prescribed Exercises of the Body for daily use for maintaining the Health in a state of integrity, for correcting any tendencies to Functional Irregularity, and for resisting the Encroachments of Disease. By ANNA L. ARNTM. Five Groups. London: Swan Sonnenschein, Lowrey, and Co. 1887.—In the introduction to the maps the authoress says: "There is an intermediate state of health, which is far more common than is supposed, and which may best be designated by the term 'negative health.' It is a condition in which one can neither lay claim to being actually ill, nor assert with truth that one is 'quite well.' .....It is to minimise the chances of break-downs, to keep at bay this negative, and perpetuate the positive state of health that is the object of these maps." Without endorsing all that is said respecting the special application of the different groups of exercises, we may say that the figures show very clearly, by means of dotted lines, the manner in which the various exercises are to be performed. The Health Maps would, in our opinion, prove very useful to those entrusted with the care and education of children, by showing how a course of useful calisthenics may be efficiently carried out without the aid of any apparatus.

Modern Gymnastics (Elementary). By A. ALEXANDER. Containing over 200 Illustrations by G. RUSHFORTH. Pp. 140. London: Philip and Son. 1887.—This work is intended as a guide to the members of the National Physical Recreation Society who cannot avail themselves of professional teaching. It consists of a series of gymnastic exercises to be performed with the usual appliances to be found in a gymnasium. The words of command for the instructor and the directions for the pupil are given for each movement, with an illustration showing the position of the pupil, and a musical accompaniment, deemed, we presume, appropriate to each exercise. We are disposed to think that some of the more advanced exercises, especially with the double bar-bells, the clubs, the bars, and the trapeze, ought not to be undertaken by delicate persons except under medical advice and careful supervision, and in all cases care must be taken not to attempt too much or to continue the exercises too long at a time.

The Physicians and Surgeons' Visiting List, Diary, Almanack, and Book of Engagements for 1888. John Smith and Co., London.—This Visiting List is now entering upon its forty-second year of successful publication, a proof that it is appreciated by those for whose use it is intended. Several new tables have been introduced and the older ones have been rearranged and extended. To those practitioners who have not as yet made themselves practically acquainted with the advantages and conveniences of this publication, we can cordially recommend its use.

ROYAL COLLEGE OF SURGEONS.

ON Thursday afternoon, Nov. 3rd, the annual meeting of the Royal College of Surgeons (of which a brief account was given in our last issue) was held in the theatre of the College, Mr. Savory, President, in the chair. There was a crowded attendance of Fellows and Members.

The PRESIDENT announced that the new room at the top of the College was advancing towards completion, the enlargement of the library would almost immediately be commenced, and very shortly the extension of the museum would be taken in hand. These additions would of course increase the current expenses of the College, and a large portion of the Erasmus Wilson legacy would be invested to meet them. The work of the Conjoint Examining Board in the new hall was carried out to the satisfaction of both Colleges.

The report was taken as read.

Mr. HOLMES moved: "That this meeting disapproves of the application for a new Charter, which, *first*, does not confer electoral powers upon Members of the College, and the right to be eligible to sit in the Council, in accordance with the resolution passed at the general meeting on Nov. 4th, 1886—namely: 'That, in the opinion of this meeting, it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education (1) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (2) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such Member for a period of ten years; (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such Member for a period of twenty years; and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows; and, *secondly*, which does not provide that no alteration in the constitution, or in the relations of the College, or in any of its bye-laws, shall be effected without the consent of the Fellows and Members convened to discuss the same, in accordance with a resolution passed at a general meeting held on March 24th, 1884, and reaffirmed at the meeting on October 29th, 1885.'" He said the length of the resolution was due to the fact that if the meeting desired it to be laid before the Privy Council it would to a certain extent tell its own tale. There had been such frequent opportunities of discussing the matter in hand amongst each other in the presence of the Council, who were kind enough to listen to their arguments, that it was perfectly unnecessary for him to go into the merits of the question. The College consisted of 13,000 or 18,000 Members, of whom 1000 were Fellows and the rest simply Members. The calculations seemed to vary. The Calendar gave the number as about 17,000, but gentlemen who had gone into the subject said that an enormous number of them were dead and had not been struck off the list, and that the real number of Members was nearer 12,000. However that might be, it appeared to be the opinion of the Council that it was perfectly just and equitable that the 1000 Fellows should have no power in the College at all except to vote for members of the Council, and that the balance of 17,000 or 12,000 should have nothing to do with the College at all—that the College should be to them of no more value or importance than if they were not Members. He considered that that was unjust and inequitable, and that opportunities ought to be given for discussing the matter with some competent and impartial authority, in the hope that things might be set right. (Cheers.) The College had acquired enormous influence, and had lately become possessed of very considerable riches. It was not right and just that all this influence and all these riches should be used by the twenty-four members of the Council for purposes on which the Fellows and Members were not to be consulted at all, which might be according to their wishes or the direct reverse. As he said before, the Members were eager for any opportunity that could be given them of arguing the matter before any competent authority, which they hoped would set it right. They must remember, however, that in whatever way things might go in the coming struggle between the Council and its constituents before the Privy Council, if that struggle terminated in their favour it did not necessarily imply that the thing was at an end. (Hear, hear.) They had two Associations, one of Fellows which was formed originally for the purpose of obtaining some alteration in the method of the election of president and also in the method of voting. The alteration in the method of electing the president was still in abeyance, but of course that Association would attend before the Privy Council and urge its views upon that subject. Besides that, the Association of Fellows joined with the Association of Members in recommending that the Members should have the power of voting for members of the Council, and it also joined with them, although by a smaller majority, in recommending that the Members should have some admission to the Council Board. He should allow the Association of Members to speak for itself, and it would, he believed, be able to show to the authority which was to grant the Supplemental Charter that they had a very strong case indeed; but he quite allowed that before an authority such as the Privy Council the influence which they might bring to bear might possibly prevail. If so, then they must turn to Parliament, and then they might feel certain that the perfectly reasonable and moderate contentions which they put forward would prevail, and that they would before long obtain the alteration which they wish to make in the Charter of the College. Certain circumstances had taken place since the last meeting, and were recorded in the report, upon which he wished to say a few words. In the first place, the resolution which had been recited in the one which he had just submitted to the meeting was the first that was passed at the meeting on Nov. 4th, 1886; and the second was: "With a view to give effect to the recommendation in the foregoing resolution, the Council is requested to empower certain members of its body to meet and confer with the representatives of the Association of Fellows and of the Association of Members." That was met by the Council with a reply, which a little surprised the Members generally, to the effect that although the Council were not prepared to act upon the recommendation contained in the first resolution carried at the meeting of Fellows and Members, the Council were prepared to act upon the second resolution so far as to appoint a small committee to confer on the subject of the first resolution with representatives appointed by the Association of Fellows and the Association of Members. That meant that although the Council would not do anything, at the same time they would tell the Members how not to do it. (Laughter.) That appeared to be so distinct a refusal that the Members did not think it worth while to spend their time, or the much more valuable time of members of the Council, in any such proceeding, and therefore the following answer had been returned: "That considering the Council had laid down as a condition of conference that it is not prepared to give effect to the recommendation contained in the first resolution, no useful purpose is likely to be served by a conference on the subject with the representatives of the Associations of Fellows and Members, but if the Council will withdraw this condition, both Associations will be happy to appoint delegates to meet the Committee of the Council." The object of the Members was to discuss the matter to see whether the terms were in any way unreasonable; and if so, to vary them, and, in fact, to let some business be done. The object of the Council was to do nothing at all but to pay the Members the empty compliment of spending half an hour in talking to them. A still more remarkable result of the meeting of Fellows and Members last year was referred to on the tenth page. The Council then issued a circular to the Fellows, in which these two questions were asked them: "In your opinion should Members of the College be allowed to vote for Fellows as members of the Council? In your opinion should Members of the College be eligible for seats on the Council?" He thought it was a very great pity that these questions were formulated in such very general terms, because they allowed men who held the same opinions to answer in perfectly different ways. He was himself an ardent supporter of both propositions—that Members should vote for members of the Council, and that Members should sit on the Council; but he could not have answered those questions with a simple affirmative, and he was not in the least degree in favour of the Members swamping the Fellows, as they must do if they were allowed to vote promiscuously. (Cheers.) Again, he was not in the least degree in favour of members of the Council swamping Fellows of the College. He could perfectly recognise that one of the great uses of the College was educational, and hitherto that had been almost the only function which the College had performed. In all

Digitized by Google

educational questions he thought the voice of the Fellows ought unquestionably to be heard, and therefore he could not say that it was desirable to answer that second question with a naked "Yes." He thought it would have been better if the proposals that had been made had been submitted to the judgment of the Fellows, although that of course could not be considered final. The Fellows were the people interested, and it was surprising to him that the judgment of the Fellows was not far more strongly against those two propositions than it really turned out to be. The number of circulars sent out to the Fellows was 987, of which twenty-one seemed not to have arrived at their destination, so that 966 Fellows were consulted by post. In return to the first question of the Council 419 Fellows voted "No," which was very considerably below the majority required; 276 actually voted "Yes"; while 260 did not take the trouble to vote at all, and therefore could not have any powerful objection to the question asked. That made 536, which was a very great majority of the Fellows. He therefore thought he was entitled to say that the majority of the Fellows had no objection to entrust the vote to the Members under such conditions as would not swamp them in their own College. (Cheers.) At any rate, it could not be said that even in the judgment of the Fellows the proposal which was carried at the meeting was in any way negatived. However, the Council, he supposed, thought that they had the sanction of their constituency, and they accordingly went on to lay the Draft Supplementary Charter before the proper authorities, but before they did so the Association asked them to meet and discuss the Draft Charter. It could hardly be said that at the meetings held hitherto anything had been discussed, except among the Members themselves. The Members talked, and the Council acted. (Laughter.) The Council, however, replied that they "do not think it expedient to convene a general meeting of the Fellows and Members to consider or discuss the proposed Draft Charter, as the subjects to which it relates have already been submitted to meetings of the Fellows and Members." It was true that the subjects had been submitted to the meetings, but whether they had been approved or not was another matter. The first provision of the Draft Charter was a very necessary one: "To enable the College to hold 'lands, tenements, rents, and hereditaments,' of annual value not exceeding £20,000, instead of £2000, as by present Charter." It seemed funny that the £2000 a year included the premises in which that meeting was held, and the partnership with the College of Physicians put them in possession of another—whatever it was. (Laughter.) Still no person would think of taking any pettifogging objection to the position in which the Council now found itself. The third provision was to empower the Council to elect to the Fellowship Members of twenty years' standing, not exceeding ten each year, on the payment of the fees required for the Fellowship examination. That appeared to be the same proposal that was protested against most strongly by the Fellows and Members. It was on the motion of one Member, seconded by another, that the general meeting said the first method recommended by the Council for widening the basis on which the Fellowship was obtained tended to lower the academic status of the diploma, and that in the interest of surgical education it was not advisable. The proposal in the Supplementary Charter tended directly to lower the academic status of the Fellowship, and ought to be protested against by every person who had the interest of surgical education at heart. The only other provision of the Supplementary Charter of any real importance was the one giving the Fellows power to vote by voting papers. One or two other matters were so remarkable that he could not pass them over when recommending the resolution. The first was the behaviour of the College in the matter of the Society of Apothecaries and the new conjoint examination. The last meeting of the Fellows and Members respectfully urged upon the Council the advisability of an arrangement for combination with the Apothecaries' Society as well as the College of Physicians, but that strong expression of opinion was only worth the breath expended upon it. The Council went on to do just as it pleased. Then the General Medical Council requested them to reconsider their policy, but the College replied in that highty-tighty, mind-your-own-business style which was so agreeable when applied to other people. That was the masterful way in which the Council of the College managed business. That state of things ought not to be permitted to continue. Matters so important to medical education and to the status of every medical practitioner in the kingdom ought not to be settled by private bodies in that way; the opinion of the profession ought to have some weight, and ought to be elicited in some way. Similar observations might be made with regard to degrees in medicine, which was one of the most thorny subjects connected with the profession. That was a matter on which the medical public ought to be consulted. How would the granting of those degrees affect men at present in practice? The only other thing he would notice was the large accession of property which the College had lately received and was expected to use for the benefit of the profession. Nobody charged the Council with anything like corruption; but there, again, they claimed to be the absolute masters of that large fund. That large accession of wealth would not make the College in the least degree more apt in the defence of the interests of the general practitioners who formed the bulk of the Members, in the amendment of the laws, nor in the abatement of any of the other crying abuses. All those matters would have to be submitted to the judgment of some impartial authority. He was very sorry it should be so—sorry to say that the Council was not in harmony with a large proportion of its members; but there was no question that such was the case. No attention whatever had been paid to the humble, respectful representations that had been made to the Council, and the Members therefore had no choice except to see whether they could not win in what had now become a simple fight. For his own part, he had no doubt as to how that fight would terminate, however long it lasted. It was not consistent with everything else that went on in this country at present to suppose that a great institution such as the College was could be entirely given up to the uncontrolled management of two dozen gentlemen (cheers), however adequately they performed their duties, and that all the rank and file should be entirely excluded. He moved the resolution with all possible confidence that it would prove acceptable to the meeting, and he trusted that they might be able to impress the Privy Council so strongly on the subject that the Supplementary Charter would be sent back for reconsideration. (Loud cheers.)

Dr. RALPH GOODING, in seconding the resolution, said he did so with pleasure mingled with sadness: pleasure, because he was raising his voice for the promotion of the welfare and future progress of the College; and sadness, because of the utter indifference of the governing powers of the institution to the crying evils and the marked indignities which had been heaped on their constituents for more than half a century. They had not only failed to redress those evils, but were now actually seeking to perpetuate them. In the report two matters were principally dealt with. In the first place, they were asked to approve of the expenditure of some £50,000 or £60,000 in additions to the College premises. That might be right or wrong, but when they found that the cost of the new dwelling house alone was estimated at something like £10,000, and that equal accommodation could readily be procured at less than one-fifth of that amount, they might fairly infer that the subject was open to discussion. Were they to conclude that consulting surgeons living in the atmosphere of metropolitan hospitals, and carrying on their profession in a West-end square or thoroughfare occupied by the aristocracy, were more competent to deal with building operations than many other Members of the College? For his own part, he believed that the leaders of the profession would do well to look for advice in such matters to the general Members who lived in the suburbs and provincial towns. The admission of Members to the Fellowship by election meant one thing and one thing only—the sale of the diploma to the highest bidder; but they were pledged to resist to the utmost any proposal which in any way might detract from the value of that academical distinction. The College was the *alma mater* of the Members, but they had been driven from their surgical home. However, they did not despair; they had a natural longing to return, and were filled with the deepest aspirations to succeed to the privilege of their surgical birthright by undertaking their fair share of the responsibility of the government and direction of the College. He trusted that the meeting would mark its sense of the justice and rectitude of the course put before them by unanimously voting for the resolution. (Loud cheers.)

Mr. GEO. BROWN thought the Council had not exercised good judgment in opposing the reasonable demands that had been put before them. They could no more control the

Digitized by Google

movement than they could stop the advancing tide, and they would again fail as they had done in their attempt to snuff out the Apothecaries' Company. In the latter case they would neither listen to the meek voice of the Members nor to the request of the General Medical Council. The result was that they had been hoisted on their own petard, and now they had a competing body whose examination would bear favourable comparison with that of the College, and whose qualification was more than equal to their own. (Laughter.) He wished to ask the Council through the President if on this occasion they would deign to do what they had never before done—attempt to reply to some of the remarks that the Fellows and Members had made. For whom did they hold the great funds that had been bequeathed to the College—for themselves, or in trust for the members? That was a pertinent question, and one that was entitled to a reply. He maintained that they held them in trust, and therefore the Members should have a voice in the disposal of those funds.

Surgeon-Major INCE said he most cordially agreed with the action of the Council in the matter of the Society of Apothecaries ("Hear, hear!" and "Oh, oh!"). He had no desire to cry down that Society; he presumed that most of those present were licentiates of it; but they were something besides, they were professional men, and he hoped something more than tradesmen. ("Question") No one would deny that the Apothecaries' Society was essentially a trades association. (A voice: "That may be, but they are gentlemen.") Wherever they had a mercenary, a commercial spirit, it must be incompatible with the spirit of a noble profession. ("Oh!") He believed there was no canker in the profession so growing and fatal as greed for money. On public grounds it was most essential that the Apothecaries' Society and the conjoint examination should be kept apart. The great want of the poor was cheap, but good, sound medical advice. (Cries of "Time.") With regard to the resolution proposed and seconded so ably, he wished to say that just in proportion as he was satisfied with the action of the Council in connexion with the Apothecaries' Society, so he was dissatisfied with their conduct with reference to the resolution. They were acting most unwisely, not only in the interests of the College, but in reference to their own interests as well. Every member of the Council must feel that the demand of the Members must be quickly answered. He cordially supported the resolution, and regretted the lamentable action of the President and Council.

The motion was carried almost unanimously, only one hand being held up against it.

Mr. JOHN TWEEDY proposed: "That this meeting respectfully requests the Council of the College to transmit a copy of the foregoing resolution to the Lord President of the Council." He said such a resolution would formerly have been out of place, but it now became in order because the Council had sent a petition to the Privy Council asking for a supplementary or renewed Charter, which did not contain any provisions which many Members who were deeply interested in the welfare of the College felt should be included in it. He would have been very glad if the difference of opinion had been settled in that room; but when he remembered how slowly political changes took place, he neither regretted nor was disheartened at the continued opposition of the Council. The executive body had come to an opinion that a certain policy was right; the general body of the Members had come to the opinion that an opposite policy was right. Year after year they had tried to settle the differences, but could not. Now the appeal was to an independent authority, and he felt that that appeal should go in a dignified way from the meeting. It was only right and just that the meeting should respectfully ask the Council to send a copy of the resolution to the Privy Council. The general body of Members were in opposition to the Council, but not in the least hostile to it. There was a fair difference of opinion, and he was quite willing to fight it out. (Cheers.)

Dr. DANFORD THOMAS said he wished to say a word regarding what the Association of Members had been doing in the interval between the last meeting and the present one. The Council had taken the question into consideration, and had consulted the Fellows. On taking the Medical Directory, which they believed to be a correct statement of those who belonged to the College and other bodies in connexion with the profession, it was found that while the College Calendar gave them 17,000 Members, in the Directory they could only discover 12,000 who were registered. Of that 12,000, something like 7000 resided out of the United Kingdom, and they had received replies from 4665, all signing the petition to the Privy Council Those had now been sent in, and were now in the custody of the Privy Council. The Association had approached the Privy Council, and had been received courteously and assured that no petition from the Council would be considered until the prayer of the Members and Fellows had also been considered. (Cheers.) He could conceive that there had been legal difficulties as to the Council giving them any direct affirmative answer. They were acting upon their Charter; they were elected by Charter under the rights which were conferred upon the Fellows in the Charter; and, standing upon their strict legal position, they thought they could not have granted the Members any rights until they had altered their Charter. The Council could, however, have put in a clause in their own petition which would have given the Members the privileges they asked for (cheers), but they had not thought fit to do so. The Association of Members would be represented by counsel at the meeting of the Privy Council, and also by deputation, and he hoped in that way the Council would be prepared to meet them favourably before the Privy Council. He had much pleasure in seconding the resolution.

Dr. ALDERSON thought it most important that they should take steps to have their views represented in the proper quarter. Last year a resolution was carried asking the Council to allow the Apothecaries' Company to join in granting a conjoint diploma, but it was perfectly useless. It was nothing to the Council to see the great number of dispensaries that were established, but it was a great thing to those Members who had to suffer from them, and also to the public who had forced upon them a number of unqualified and ignorant men. No doubt some of these dispensers held the diplomas of the College, but they must be taught not to act in a way that was injurious to the great body of Members and was also prejudicial to the public weal.

Sir JOSEPH LISTER, who was received with loud cheers, said he feared that what he was going to say would not seem at all acceptable. With reference to whether the resolution would be likely to be acceded to by the Council, it must be distinctly understood that, so far as the individual members of the Council were concerned, they must hold themselves perfectly free to discuss that question when it came before them as a Council. (Cries of "Oh, oh.")

Mr. JOHN TWEEDY said, as mover of the resolution, he did not of course wish it to be implied that any answer was to be given at once. He understood that the Council were present more in a complimentary way, and that the President was simply there to report the wish of the meeting to the Council, and then in proper course it should be considered and decided upon. (Cheers.)

The PRESIDENT said he thought it was quite understood.

The resolution was then put, and declared to be carried unanimously.

Mr. ERNEST HART said that every duly constituted meeting had a chairman, and in this case it had also a secretary. He asked, as a point of order, whether it was not the absolute and customary duty of the president or chairman of any meeting and its secretary to transmit to any authority any ordinary document which in that capacity they were requested to transmit.

The PRESIDENT ruled that Mr. Hart was entirely in the wrong. This was a meeting called to consider the report of the Council. It was not within the province of the meeting to take action of this sort. The Council was the executive body of the College, and it was their duty, and their duty alone, to take action of this kind. The resolution itself was perfectly in order, and it would be considered by the Council.

Mr. ERNEST HART moved that the resolution already passed be placed in the hands of the Chairman of that meeting and of the Secretary, with the request that they would as such transmit it to the Privy Council.

The PRESIDENT said that he could not put the resolution, because it was not within his province or the scope of his authority to do this without bringing it before the Council.

Mr. JAS. DAY asked when the Members would know what action the Council were going to take in the matter.

The PRESIDENT said he would take care that the resolution was brought to the notice of the Council with the least possible delay. The Council had certain prescribed times for meeting. How long the subject would take in deliberation he could not say, but Members could obtain any information that was required by applying to the Secretary.

Dr. PROSSER JAMES asked, with reference to the point of order just raised, whether this was a meeting of the Royal College of Surgeons of England or not, and also whether the President of the meeting was President of the Royal College or simply of the Council?

The PRESIDENT said these questions were easily answered, but they did not touch the point at issue, which was simply this—that the Council was the executive body of the College, and it was for the Council to determine their action with regard to this request, which had been most properly put to them.

Dr. JAMES.—And a meeting of the whole body of the College has no authority?

The PRESIDENT.—Certainly not of that kind.

Dr. JAMES.—No authority after it has passed a resolution to say what shall be done with that resolution?

The PRESIDENT.—Certainly not. (Laughter.)

Dr. COLLUM called attention to the statement in the report which recommended that No. 38, Lincoln's-inn-fields, now let in chambers and producing an annual rental of £368, should be pulled down and converted at an expense of £3000 or £4000 into a residence for the conservator. He thought the better plan would be to give that gentleman an extra £100 or £150 a year to find his own residence instead of practically adding £600 a year to the expenditure of the College for that purpose. The residue could be utilised in scholarships for the profession and for the sons of poorer men. The income of the College was £35,000 a year, derived from diplomas and fees. Last year the Members paid £22,859, while the contributions of the Fellows of the College on the Council was only £84. The examiners and the Council received £9685 15*s.* last year for their services, and that was why it was the Members were kept out. (No, no.) There was scarcely a Member of the College of Surgeons who could not influence more or less a member of Parliament (Hear, hear), and he hoped that everyone would endeavour to do so. The Marquis of Hartington lately said: "The Government under which we now live is as near an approach to a pure democracy as exists anywhere. The House of Commons practically controls the Government, the House of Commons is elected by the people. It is in the power of the House of Commons to displace the Government, and it is in the power of the people at no distant date to displace the House of Commons." He hoped that each Member of the College would address his member of Parliament and request him to appeal to the Government on this subject (Hear, hear), and then the matter would soon be settled.

On the motion of Mr. BRINDLEY JAMES, seconded by Surgeon-Major INCE, a vote of thanks was passed to the President, and the proceedings were brought to a close.

MEDICAL HISTORY OF THE EUROPEAN TROOPS IN THE BOMBAY COMMAND DURING 1886.

IN the report by W. A. Thomson, M.B., Surgeon-General, Bombay, upon the health of the European troops in the Bombay Command during 1886, the average strength for the year is stated to have been 11,000. The admissions into hospital were in the ratio of 1488, the deaths of 12·73, the invalids sent to England of 28·09, and the constantly sick of 73·98 per 1000. Compared with the results for 1885, there has been a slight increase in the admissions, but a very marked decrease in the deaths, amounting to nearly one-half. This remarkable reduction in the mortality does not, however, appear to have been the result of any alteration in the health conditions of the troops in the Presidency, but of the transfer of Quetta, at the end of the first quarter of 1886, from the Bombay to the Bengal Command. If the force at Quetta be deducted from the returns of both years, the death-rate in 1885 will be 12·49, and in 1886 14·16 per 1000, exclusive of the deaths of invalids on their passage home, thus showing an increase of 1·67 per 1000 in the latter period. There has been a decrease of about 1 per 1000 in the invaliding, and an increase of 7 per 1000 in the constantly sick. The admissions ranged between 1102 at Kirkee and 2387 at Asirgarh, and the deaths between 3·87 at Ahmednagar and 30·30 at Ahmedabad. The most fatal disease among the troops was enteric fever, which gave rise to one-third of the deaths; the admissions by it were in the ratio of 12·2, and the deaths of 4·18 per 1000. The stations at which it was most prevalent were Karachi, Deesa, Nasirabad, Poona, and Mhow. Deesa furnished the largest number of deaths. Aden, Satara, Asirgarh, and Indore were the only stations at which no case occurred. The months in which it was most prevalent were May, July, September, and October; the greatest number of deaths occurred in September. At none of the stations could the disease be traced to any specific cause. At Poona the medical officer "thinks the most probable source of the disease was 'the effervescing and sherbet drinks produced at the shops kept by natives,' and from impure water." At Karachi, although no defects were found in the barracks and their surroundings to account for it, the Principal Medical Officer says: "Much remains to be done to perfect the sanitation of Karachi. ..... At present it is simply 'honeycombed' with cesspools." The cases of enteric fever occurred chiefly, though not exclusively, among the young soldiers and the recent arrivals in India. Bombay enjoyed nearly an exemption from cholera, only 4 cases having been admitted, of which 3 died, and there was also a death at Karachi out of hospital. Two of the fatal cases occurred at Deolali, and one at Quetta, and the other admission was at Indore. Malarial fevers were the cause of one-fourth of the total admissions, but of only one death. With the exception of Quetta, which, as before stated, was occupied for three months only by Bombay troops, they were most prevalent in the Mhow division, and next to it in Sind.

There were 7 suicidal deaths recorded, and 1 homicidal. Of the former, 6 were by gunshot and 1 by hanging, by means of a piece of "puggree," while confined in the cells at Aden for drunkenness. The homicidal death was that of a private of the 2nd Lancashire Fusiliers at Nasirabad, who was shot by a comrade while trying to disarm him.

The death-rate of the officers was 8·29, of the non-commissioned officers 22·79, and of the privates 12·54 per 1000 of strength; and the invaliding was 44·20, 42·84, and 28·69 in these grades respectively.

Early in 1887 certain lock hospitals which had been closed were reopened, "and already the influence of these institutions is observable in the diminished admissions to station hospitals for venereal diseases. Sanction has also been awarded by the Government of India to the establishment, for the first time, of lock hospitals at Hyderabad and Satara," and it is anticipated that they will have an important influence in reducing the proportion constantly sick of the troops.

"PARALYSIS OF THE ABDUCTORS OF THE VOCAL BANDS."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Felix Semon, I beg to state that I had no intention of exhibiting a table of all cases published. The standard writers (Mackenzie, Ziemssen, &c.) on diseases of the larynx have not considered it necessary to include any similar table in their account of this important disease. Having collected more than double the number given by Burow in detail, I decided that this amount was quite sufficient for my purpose. I am extremely sorry that Dr. Semon's cases did not happen to come to hand amongst those sixty. Had they done so, I should assuredly have published them inpreference to many of the others. A considerable number of the instances I met with were omitted on account of insufficient detail.

Amongst the innumerable experiments on the subject of laryngeal innervation, those of Claude Bernard, in refutation of Bischoff, have always seemed to me incontrovertible; nor can I easily consign them to oblivion. Since, however, Professor Horsley's skilful experiment has finally satisfied Dr. Semon, the matter certainly demands attentive reconsideration.

Let us set another experiment by Bernard beside this one of Prof. Horsley. In a kitten five weeks old *both* spinal accessory nerves are cut. The animal becomes voiceless, but is otherwise unaffected for two days, when both recurrents are severed. Instantly it dies from occlusion of the glottis. Does not this seem to prove incontrovertibly that the vagus has a motor power not derived from the spinal accessory? In the face of such conflicting evidence I do not think Dr. Semon's expression "certainly erroneous" at all justifiable. I am, Sirs, yours obediently,

Finsbury-square, E.C., Nov. 8th, 1887. GORDON HOLMES.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 12, 1887.

WE have repeatedly drawn attention to one of those evils incidental, shall we say, to a somewhat over-ripe civilisation, with which the public mind is becoming increasingly prone to divert itself. This is the practice of self-medication—a practice which we are assured will make but little headway among a rational and simply living population, in spite of the copious fair speech of those who foster it, while it is denounced as it should be by the common voice of the medical profession. Faith in the reason, nay in the very instincts of mankind, and in the better judgment of our professional brethren, forbids us to doubt that this disguised enemy of health will eventually stand forth as a revealed imposture. This consummation is, however, the hope of an enlightened future. Meanwhile the possibilities of present mischief cannot be ignored. That these are not hidden from the majority of practitioners we are well aware, as also of the fact that many intelligent persons outside our own calling have a general sense of their existence, though the feeling is by no means as widely diffused as it ought to be. We are particularly conscious, however, of what, at all events, appears to be a very imperfect perception of these possibilities on the part of some medical men.

A feature in the recent development of literature has been the appearance of popular journals of a quasi-medical character, and the practice on the part of some of our lay contemporaries of devoting a part of their columns to the details of medical treatment. The function of these periodicals consists in an endeavour to enlarge the sphere formerly occupied by the time-old, though we cannot say time-honoured, agency of nostrums. They assume to administer, not medicines indeed, but medical advice to the public, one and all, for one penny! There is little concern for the greatly varying condition of the great army of patients—for the pulse which throbs in one and flickers in another, for the whole heart or the maimed heart, for the sound or loaded kidney, for the bloodvessels, whether they be well-nigh invulnerable in the vigour of untried youth or decaying at the brain after a life's worry. None of these things matter: the chloral, the colchicum, or the opium goes down all the same; there is the rest or the horse exercise, the full or the light diet at choice (the patient can have which he chooses, for he must know what is wrong with him), and the proprietor and the publisher are the gainers. This is what we may call the likeness in plain clothes of the newest departures in journalistic literature. Thus displayed, perhaps it may shock some, and the fact that it has not hitherto awakened more generally a natural instinct of caution is simply due to a wide-spread misunderstanding of its true meaning. If this be true of the public generally, is it remarkable that it should be in some measure true of a limited number of medical men, and—we say it with much regret—of some whose intellectual grasp and whose high sense of professional honour might have saved them from what is seen on its exposure to be so great an error? But here, again, we are certain there has been misunderstanding. The members of our profession are sometimes accused of a want of business capacity, and the accusation is partly true. Particularly is it likely to be true of those who are by their very scientific eminence debarred somewhat from the concerns which constantly occupy the purely practical man. It may be that we are to trace in this fact the cause of the regrettable indiscretion which has appended to the literature in question the nominal sanction at least of reputable practitioners. Such men would never commit themselves to such a course with their eyes open. It is to our mind far more probable that, having regard to the fact that certain general principles and certain details of hygiene or common-sense domestic management may be freely expounded without risk of misconception, they have allowed themselves to be announced as public instructors in medicine and surgery. Their distinct intention is doubtless to stop at the limit they assign themselves, but they forget to question whether this is also the design of the lay editors who solicit their literary assistance. Yet this matter is an all-important one, and there is no guarantee that they will be able to stop in their present course. There is also another consideration to which we wish to direct attention. It is this. The ground which is to be covered by the new teaching is no neglected field. It is already supervised by careful and competent visiting practitioners, not a few of them equally skilful in diagnosis and successful in the execution of practical detail. Is it wise to substitute for the care of these acute observers, working on the spot, the comparatively mechanical action of oracular dicta delivered through the popular press? We are certain that it is not, but that here we have a proceeding related, and not very remotely, to the practices of the nostrum system, and, like them, of more than doubtful advantage to the public. Let us, in conclusion, make one other suggestion, which, if it should wound, is not, we hope, too late to exercise a curative purpose. It appears to us that certain names, towards which we feel as medical men a brotherly attachment, have gained nothing, and have given nothing towards the honour of our common profession, by being found printed with ample fulness of description on broad sheets intended for universal distribution. Here, beyond question, we have advertisement on an extensive scale, and prejudice is evidently done to others equally qualified for public recognition, but deterred by a sense of justice and professional propriety from accepting it under these conditions. We cannot but think, however, that in many cases, where names and explanatory directions have been published with the same liberal disregard of professional usage, the practitioners have not been consulted in the matter.

In the foregoing remarks we have endeavoured to intimate what we conceive to be the true line of action to be adopted by medical men in the face of tendencies which, however permissible in commercial life, are incompatible with the safe and honourable conduct of medical practice. The temptation to fall in with such tendencies is, we grant, in the present age of fierce competition and general depression, considerable. We would strongly counsel, however, that

Digitized by Google

the temptation should be resisted The reward of patience will be richer when it comes, and almost any reform in existing arrangements, with a view to affording a practical outlet for professional energies, would be preferable to a system of popular prescription which too often combines the chance treatment of disease with a form of open and precise advertisement.

IN the present day we have become so accustomed to rapidity of execution in most matters that we can well imagine that, owing to the delay in its publication, the report of the Cholera Commission sent to Spain two years ago by the Royal Society and the Association for the Advancement of Medicine by Research may be received with less interest perhaps than it merits. It is true that nearly a year ago the Commission made a preliminary report to the Royal Society, and the delay in the issue of the complete report, which appears as one of the pamphlets of the Association,[1] is explained by the desire of the members to incorporate the results of a subsequent inquiry on the subject, conducted by Dr. SHERRINGTON in Italy in 1886. As this addition makes an important correction in the general result, it is not altogether to be regretted that Drs. ROY, GRAHAM BROWN, and SHERRINGTON have taken time before submitting their conclusions to criticism. The general impression gained on reading the report is that it has been drawn up with candour and painstaking care, but that its results are disappointing, and, indeed, somewhat barren. It cannot be said to have advanced our knowledge of the pathology and etiology of cholera; but for all that it is worthy of careful attention, since it deals with the subject in a spirit of impartiality, which is too often absent in similar inquiries.

The report opens with a brief sketch of the researches upon micro-organisms and cholera, from KOCH'S discovery of the comma bacillus onwards, the support accorded that discovery by VAN ERMENGEN, NICATI, and RIETSCH, and the adverse conclusions of KLEIN and GIBBES. Whilst admitting the fact that the introduction of the comma bacilli into the intestine of guinea-pigs is to produce diarrhœa and often death, it is held that the disease so produced, which is accompanied by free development of the bacilli in the canal, is not identical with cholera; at the same time it is not septicæmia. This statement forms, as will be seen, the groundwork of the conclusion arrived at by the Commission with respect to the position of the comma bacillus in the disease. Before adverting to this it will be convenient to follow the investigations which were made by the Commission in Spain, whither it was sent to reconcile if possible the contradictory views put forward by KOCH and his followers on the one side and Drs. KLEIN and GIBBES on the other. Post-mortem examinations were made on twenty-five cases, at the shortest possible interval after death, and with all due precaution to avoid external contamination. Nothing of importance was added to our knowledge of the morbid anatomy and histology of the disease; although it is curious that whereas in Spain the intestines very rarely presented evidence of ulceration and catarrh, in Italy ulceration and sloughing were very frequently met with. The absence of signs of catarrh in most cases is adduced as evidence that this is not an essential part of the choleraic process; and further that the intestinal flux is not due to irritation of the mucous membrane, but to hyper-secretion similar to that produced in MOREAU'S experiment of section of the mesenteric nerves. Hence it is inferred that the cause of cholera, if an organised ferment, is more likely to be found in the mucosa itself or its nerves than in the intestinal contents. Naturally the greatest interest attaches to their researches upon the micro-organisms met with in this disease. Comma bacilli were found in the fluid and mucous flakes in all cases, with the exception of six or seven; and although it is possible that a more extended search would have revealed their presence in these cases, yet it is noticeable that in the majority these organisms were decidedly sparse, and certainly not in excess of other microbes. These other organisms included a small diplococcus of especially frequent occurrence, and "numberless varieties" of straight bacilli. Cultivations on the methods of KOCH also confirmed the fact of the scarcity of comma bacilli, which even KLEIN and GIBBES had found to be more constantly present than this Commission has. The same departure from KOCH'S results was obtained in their examination of the mucosa itself; for their "results confirm fully those of STRAUSS and KLEIN as to the absence of any comma bacilli in the mucosa of the lower or other parts of the small intestine in the great majority of cholera cases"; and no confirmation was obtained of KOCH'S statement of the number present in the mucous membrane bearing any definite relation to the acuteness or severity of the attack. It is plain, therefore, that, on the grounds adduced by KOCH, the Commission cannot accept his inference on the causal relation of the bacillus to cholera.

Another branch of this inquiry was with respect to the method of protective inoculation introduced by Dr. FERRAN of Valencia. Dr. FERRAN himself was not seen, but several specimens of his culture fluids, which had been sent by the Spanish Government to Aranjuez for the inoculation of soldiers, were examined for micro-organisms. They did not contain the peronospora-like bodies described by FERRAN, but were impure cultures of various forms of bacilli and micrococci. With admirable justice the reporters admit that these cultures may have been contaminated after leaving Dr. FERRAN'S hands, but it is quite evident that they are unable to rely upon the accuracy of his observations, whilst they do not hesitate to point out the risk of septicæmia to which those inoculated with these impure cultures were liable. As regards the other microbes discerned in cholera (the straight bacilli of EMMERICH and of KLEIN), the results of this inquiry are quite negative. EMMERICH'S bacillus was not discovered by following his methods, and it is concluded that it is a septicæmic form accidentally present in certain cases.

So far, then, the inquiry seemed to issue only in a failure to confirm previous observations; but the considerations above adduced upon the probable seat of the virus led the Committee to a diligent search for evidence of the presence of a micro-organism in the mucous membrane. Granules stained red by fuschin, like the nuclei cells, were observed in this tissue, but no significance was attached to them until they happened to be detected in the kidney of one case, in

[1] Kolckmann, price 6d.

Digitized by Google

the lymph space outside the membrana propria of one of the tubuli contorti. The granules there seemed to be nodal swellings in a fine filamentous network or mycelium. By adopting other methods they went back upon their specimens, and eventually demonstrated the presence of this or some allied structure in every one of the twenty-five cases. That it could not have been introduced by accidental contamination after death was evident from the depth at which it occurred, and the fact that some of the examinations were made immediately after death; and the precautions adopted were such as to preclude such contamination. The first opinion as to the nature of this parasite—viz., that it belonged to the chytridiaceæ, which Mr. GARDNER had believed—has been modified by that gentleman, who now thinks that it is an involution form of some bacillus. But its precise significance remains in doubt. In not one of the specimens obtained in 1886 in Italy could it be found, so that those who may have thought that herein lay the cause of the disease are doomed to disappointment. Hence it is that the investigation has been comparatively barren; but, singular to state, it has not materially weakened the position of the comma bacillus. For in their "conclusion" the investigators state that not only is it a distinct species, but that it is distinctly related to cholera. (There is an unfortunate omission of the word "not" in a passage relating to this on p. 19.) For although their inquiry has led them to discard the idea that it is the direct cause of the disease, they cannot regard its presence as either harmless or accidental. They suggest that it does bear a causal relation to the premonitory diarrhœa, and is therefore an indirect cause of cholera, to which such diarrhœa disposes. Yet even this qualification is further qualified by an expression of regret that their inquiries in Spain "had not advanced sufficiently far to convince us that KOCH'S comma bacillus was not the direct and only cause of cholera," and that they therefore did not study the micro-organism of the dejecta from cases of premonitory diarrhœa.

THE benefits which have been conferred upon the English people during the fifty years the QUEEN has ruled over this country have been during the present year the subject of universal attention. The Empire has prospered and grown, the necessaries of life have been rendered more available for all, and there has been a steady advance in the social improvement of the people. Perhaps the public health administration, which has had its birth in this period, has been more instrumental in fostering this social improvement than any other power which has been in force. Work such as that undertaken by the late Lord SHAFTESBURY, and which aimed at the promotion of cleanliness of mind as well as of body, had its natural outcome in the scientific study of the means of preventing disease. The admirable address which Dr. THORNE THORNE, the newly elected President of the Epidemiological Society, delivered on the 2nd inst. places forcibly before the profession, and we hope before the public, the great gain that has accrued to the population from our better knowledge of the etiology of disease and of the requirements of life.

Dr. THORNE properly claimed for our system of registration of causes of mortality that it was the beginning of preventive medicine. Until it was possible to know with some precision the proportions in which the population died from different diseases, the effects of conditions inimical to life could not be appreciated. To the admirable development of that system at Somerset House, and to the accuracy of the reports which emanate from that department, we are indebted in no small degree for the progress of which Dr. THORNE was able to give account. It made possible to be known the duration of life in country districts and in large towns, and has given opportunity for the local circumstances which gave rise to an undue mortality to be accurately studied.

England may without boasting claim that she has taken the lead not only in gaining knowledge of the conditions which are concerned in the production of particular diseases but that she has also been first in modifying her laws and in creating a public health administration in response to this teaching. Dr. THORNE took as an illustration of the benefits which had been conferred on the community by these changes the reduction in the death-rates from certain special diseases. Fifty years' experience of small-pox had provided data by which the extent of the usefulness of vaccination might be better defined. The Vaccination Acts passed in Queen VICTORIA'S reign had led to a vast saving of life, and especially of child life, and these had especially protected those who are unable to guard their own interests. "Fever" had been found to consist of at least two different diseases—typhus and enteric fever; the former largely due to the crowding of people in houses and of houses on a site where air and light were shut out; the latter mainly due to excremental pollution. Each required its special means of prevention, and these had been applied with astonishing results. London had spent fourteen millions of pounds in the improvement of unhealthy areas, and among the results might be cited the almost complete disappearance of typhus from the metropolis. Enteric fever had enormously diminished, and this had been brought about through the adoption of methods which the new knowledge showed to be necessary. Further investigation had indicated the different channels by which disease could be disseminated; BALLARD and MICHAEL TAYLOR had demonstrated the part that milk could play in the diffusion of enteric and scarlet fever; POWER and KLEIN had shown how milk-scarlatina had its origin, and had proved the urgent need for human and veterinary medicine to work together for the saving of human life; BUCHANAN had taught that phthisis, the scourge of the British Isles, was chiefly dependent upon conditions of soil which could be removed. These are but a few examples of the additions to knowledge which the work of the last fifty years has produced. Not least in importance must be reckoned the development of a system of precise investigation, which will confer in the future even greater benefits than those experienced in the past, and to the perfecting of which the new President of the Epidemiological Society has conspicuously contributed.

Dr. THORNE, at the conclusion of his address, not unnaturally touched upon the complaint of some that the country is already over-populated, and that the saving of life which was being effected was already creating difficulties which must increase as time went on. To this he had a sufficient reply. Preventive medicine aimed not only at the reduction

Digitized by Google

of death-rates, but at the diminution of disease; the result, he said, of applying its principles to public health operations had conduced to individual and national prosperity, to greater enjoyment of life, and to capacity for greater power for remunerative occupation. There is, indeed, no question that happiness is brought to the greater number by the diminution of disease and death; and it may be said of the Victorian era that in this period the work necessary to effect this object was first seriously undertaken by the State.

IT is not amiss at this early stage of the session of our various Medical Societies, metropolitan and provincial, to suggest one department of medical knowledge to which they do not make so many contributions as is desirable. The little attention that is given in our Societies to therapeutics, including the action of medicines, is remarkable, and is not a little to be regretted. For one thing, surgery has a large share of the time and attention of our Medical Societies. Dr. BURNEY YEO, at the last meeting of the Clinical Society, humorously complained that the great cavities of the body, in which the physician used to see a safe domain for the exercise of his art and the operation of his prescriptions, were being invaded one by one by the surgeon. The brain had gone over to his care, the thorax was not safe from his interference, and now even the abdomen was threatened with surgical procedures which would supersede and eclipse the more indirect and mysterious methods of the physician. There is a considerable amount of truth in this view. But the physicians are not so discredited after all. It is by their careful diagnosis and their discriminating pathology that cases are defined and the line of treatment is indicated. The surgeon in such cases is, as it were, the complement of the physician, who sees in aspiration or laparotomy a more ready way of removing the consequences of inflammation than by the old antiphlogistic and absorbent routine. But after allowing fully the brilliant part played by surgery even in the cure of internal diseases, hitherto left almost solely to physicians, it is surely true that physicians too readily abandon the Societies to the surgeons, and refrain with much modesty from discussions on the medical aspect of therapeutics. It is impossible to deny that therapeutics has undergone a very great development of late years. The action of drugs is better understood, and so is the action of foods. But if we look into the Transactions of our great Societies for any contribution on the action of medicines, we shall look almost in vain. Take, for example, the last admirable volume of the Clinical Society's Transactions: there is but one paper of a conspicuously therapeutical kind, and that is the work of a surgeon. Mr. TREVES describes a case of glandular disease in a patient over sixty. Numerous enlarged glands occupied both sides of the neck, from the jaw to the clavicle. Mr. TREVES might have taken his knife to remove them. But instead of taking his knife, like a surgeon, he took his pen, like a physician. He prescribed arsenic, and the tumours vanished. He was as confident that he had removed the disease with arsenic as if he had removed them surgically. His words were: "I think it would be safe, quite safe, to infer that the cure was entirely due to the arsenic"; and in support of his contention he adduces evidence of the curative effect of arsenic in certain malignant or quasi-malignant gland tumours from a striking paper by Dr. KOBEL of Tubingen. Of fifty-nine such cases, seventeen were cured. The action of the same drug has been the subject of a very suggestive communication to the same Society during the present session by Dr. HANDFORD of Nottingham. Dr. HANDFORD brings out strongly some effects, hitherto little regarded, to be obviated if possible, and which constitute a subject for careful and continuous consideration.

There is evidence, on all sides, of life and activity in therapeutics. Surely it should find more expression and discussion in our Medical Societies. So much is this defect felt in some quarters, that a new Society is being constituted, to devote itself solely to therapeutical questions. Would it not be much better to use the Societies at present existing, which abound in men rich in knowledge of the action of drugs? Some of us can remember that the Clinical Society, in particular, was started to be, above all things, therapeutical. Sir THOMAS WATSON emphasised the necessity for such a direction of its work in the Inaugural Address which adorns and initiates the Transactions. The Society has well justified its existence, but scarcely in this particular direction. It has not yet realised the mission prescribed for it by Sir THOMAS WATSON, "to bring up the therapeutic departmental of medicine to a nearer level with those other parts which are strictly ministerial and subservient to this." Surely every Medical Society should have a Therapeutical Committee, whose special function it should be to take note of the action and uses of medicines, and the forms in which their best effects might be attained and their deleterious action minimised. At any rate, such a function should be cultivated by a Society whose formation excited in the mind of Sir THOMAS WATSON a belief "that it will hereafter be spoken of as the starting-point of a vast and solid improvement in that which is our special office in the world—the scientific and intelligent exercise of the divine art of healing."

Annotations.

"Ne quid nimis."

THE ANNUAL MEETING AT THE ROYAL COLLEGE OF SURGEONS.

THE annual meeting of the Fellows and Members of the College on the 3rd inst., of which we give a report elsewhere in our issue, in years to come will be memorable on account of the unanimity which characterised the proceedings, and that, too, notwithstanding the presence of many independent Fellows and Members—that is to say, of Fellows and Members not affiliated with either of the Associations. Not a single voice was raised in defence of the *status quo*, behind which the present Council so stolidly shelter themselves. Another circumstance of considerable interest was the impatience manifested by the meeting during the speeches of one or two speakers who wandered from the subject matter of the meeting. On such occasions as the annual meetings it is quite impossible to discuss details. Broad and general principles only can be adequately advanced, and these must be placed in the hands of the ablest men that can be secured for the purpose. Nothing but harm can result from individual attempts to discuss large questions such as those now at issue. Those who would discuss these questions should join one or other of the

Digitized by Google

Associations, and regularly take part in their meetings, which can be held as often as may be desirable, or until some general principle acceptable to a large majority has been established. This impatience was in marked contrast to the attention with which Mr. Holmes' incisive summing up of the questions at issue, and the conduct of the Council in ignoring all suggestions made to them from without, was listened to by the meeting. Almost by the time this comes to our readers the deputations from the Associations of Fellows and of Members will have been duly received by the Lord President of the Council, and we shall wait the result of these conferences with great interest. It is difficult to believe that the struggle can end otherwise than in a manner favourable to the Members. As Mr. Holmes said, it was neither just nor equitable that the 1000 Fellows should have no power in the College at all, except to vote for members of the Council, and that the 12,000 Members should have absolutely nothing to do with the College. The College exercised enormous influence, and was now possessed of very considerable riches. It was not just or proper that this influence and all these riches should remain under the sole control of twenty-four members of Council. Mr. Holmes' speech is worthy of very careful perusal; his arguments appear to us quite unanswerable, and we cannot doubt that they will receive every attention at the hands of the Lord President of the Council.

FEVER IN LONDON.

THE epidemic of scarlet fever in the metropolis shows a trifling decline, the number of cases admitted into the Metropolitan Asylums Board hospitals during the week ending Nov. 4th being 265, or 3 less than during the preceding week. The number of admissions also up to Wednesday last gives rise to the belief that this decrease may continue, since on Monday 46 cases were admitted, compared with 64 on the same day of the preceding week. There are, however, a greater total number of cases of fever in the hospitals than at any period of the epidemic, there being 2535 cases of scarlet fever, 127 of enteric fever, and 26 persons suffering from other febrile diseases. Two cases of small-pox were removed during last week to the hospitals from the districts of Rotherhithe and St. George's-in-the-East. This disease is, indeed, showing a tendency to spread which may well give rise to some anxiety. On Thursday of last week there were as many as ten patients suffering from small-pox under treatment in the hospital ships. During that week one death occurred from the same malady at Bristol, one at Birmingham, and nineteen at Sheffield, where there is a considerable epidemic. Small-pox is therefore showing some signs of becoming generally diffuse, and this occurring at the present period of the year makes it more probable that the extension will continue.

PHYSIOLOGICAL ACTION OF CHROMIUM.

DR. HEINRICH PANDER, of Dorpat, publishes an account of some researches he has made on the physiological action of chromium. The compound which he found to answer best was the double lactate of chromium and sodium. Chromic acid and its salts produced both acute and chronic symptoms, salts of chromic oxide causing only chronic or, at most, subacute forms of poisoning. The chromic acid compounds were found to be a hundred times more toxic than those of chromic oxide. The acute forms of poisoning show themselves by the disturbance of the respiration and of the central nervous system; chronic forms affect the skin and also the mucous membranes when air containing finely divided chromic oxide is allowed to come into contact with them. The heart's action was not directly affected by any of the preparations. The chief as well as the earliest morbid changes appeared in the kidneys under the form of parenchymatous nephritis, followed by the interstitial form; also in the gastro-intestinal tract, where inflammation, ecchymoses, and swollen follicles were found. There were also morbid appearances in the blood and the spleen. In chronic cases the spleen was shrunken and the hepatic parenchyma had a cloudy appearance. Chromium was found to be absorbed both when given hypodermically and also when administered by means of the gastro-intestinal tract, at least when soluble compounds were employed. Chromic acid preparations were absorbed with great rapidity, both by the skin and the stomach. When in very small quantities chromic acid and its salts were reduced to chromic oxide. The elimination of chromium took place mainly by the kidneys, but also to some extent by the liver and bowels. Death was caused in acute cases by arrest of respiration and disturbance of the central nervous system; in chronic cases by morbid changes in the blood, the kidneys, and the digestive tract. Dr. Pander was unable to find any indication as to the value of chromium as a therapeutic agent.

VICTORIA UNIVERSITY AND THE YORKSHIRE COLLEGE.

AT a meeting of the Court of the Victoria University on the 3rd inst., the application of the Yorkshire College, Leeds, to be admitted as a College of the University, was discussed on a report from the Council. For admission it is necessary that full provision for instruction in Arts, Science, and Medicine should be made to the satisfaction of the Court of the University, and as the curriculum of the Yorkshire College did not completely fulfil the requirements of the Council on the Arts side, Professor Adamson practically moved the rejection of the application. We are pleased, however, to say that broader and wider counsels prevailed, and, on an understanding that the curriculum in Arts would be extended, the application was accepted. The fusion of the three northern Colleges and Schools of Medicine into a Northern University is now complete, and the history and progress of the University since its foundation show clearly that nothing but good has resulted. A remarkable impetus has been given to the higher education in the north of England, and the anticipation of those who expected a downward rivalry in degrees from the "branding of its own herrings" by the new University has been completely falsified. We question if degrees are given on fairer terms or on a more honest and thorough curriculum than at the Victoria University. The combination of external examiners with the professors and teachers in the University has worked thoroughly well, and has led to no friction. The success of the Teaching University of the north of England is a good omen for those who urge the formation of institutions on the same lines for London and for the Midlands.

THE SANITARY CONDITION OF BETHNAL GREEN.

THE public inquiry into the sanitary condition of Bethnal Green, ordered by the Home Secretary, was continued this week by Mr. D. Cubitt Nichols and Mr. Shirley Murphy, the Commissioners appointed for this purpose. Evidence was given by Dr. Bate, the medical officer of health, by the surveyor, sanitary inspectors, and a member of the Sanitary Committee, as well as by Dr. Louis Parkes, who had been engaged in the inspection of the district on behalf of the Mansion House Council on the Dwellings of the People. The Commissioners have also visited many of the localities which were the subject of complaint, and are still continuing their inspections. Associated with them in these duties are two vestrymen, who have been appointed by the Vestry of Bethnal Green at the request of the Home Secretary.

THE ROYAL BERKSHIRE HOSPITAL.

THE election of a physician to the Berkshire Hospital took place on Tuesday, Nov. 1st, in the presence of an unusually large assembly of the governors of the hospital, brought together by the interest excited in the election by the publicity given to it in our own columns and in those of the local press. It is the privilege of the medical and surgical staff of the hospital to select from among the various candidates and recommend the two most eligible to the governors. This accordingly was done. The two candidates selected were Dr. Burgess and Dr. Moody Ward. On the day of the election it transpired that Dr. Burgess had retired, and that Dr. Moody Ward was the only candidate remaining. It was, however, announced at the meeting that the medical staff did not consider him eligible. One of the governors, who is known to take a great interest in the hospital, proposed that the election should be postponed. It is difficult to reconcile the action of the medical staff in recommending Dr. Moody Ward as one of the two most eligible candidates, and, when his election was rendered inevitable by the retirement of the other candidate, in pronouncing him ineligible for the appointment. Their inconsistency was at once evident to the governors present. An amendment was proposed by one of the vice-presidents and seconded by another, that the meeting should proceed to the election of Dr. Moody Ward. The Secretary was directed to read this gentleman's testimonials, and his claims to the appointment were considered unimpeachable by a large majority of the governors. He was therefore elected in opposition to the recommendation of the medical staff, but, we believe, to the satisfaction of the large body of practitioners who interested themselves in the election.

THE FORGOTTEN WORTHIES OF MEDICINE.

A VOLUME might be devoted to this theme, and one of its most interesting chapters would be descriptive of the heroic life and death of Eusebio Valli. That gifted Tuscan physician, whose anticipations of Pasteur's prophylactic treatment of rabies have already been noticed in THE LANCET, met his death at Havana in circumstances which do honour to himself and to his calling. From his Oriental experience with the plague, he had convinced himself that inoculation might be extended to yellow fever—as, indeed, it has quite lately been by Dr. Freire at Rio de Janeiro. In 1815 he was acting as ordinary physician to the Military Hospital at Dijon in France, and, with the sanction and aid of King Louis XVIII., he set sail on December 14th of that year for America to put his theory to the proof. Arrived at Philadelphia, he had an interview with the celebrated Dr. Moore, who warned him against the attempt; but Valli made the characteristic reply: "Believing in the contagious character of yellow fever, I propose to inoculate myself with the perspiration of the moribund from that disease, and also with the bile taken from their dead bodies, modifying the poison with the selfsame reagents I employed in my experiments on the plague of the East. If it is inscribed in the Book of Fate that I am to fall a victim in this great ordeal, my death will not be without honour." In 1816 the yellow fever did not visit North America, so Valli set out for Havana in quest of patients suffering from the malady. He presented himself to the public health authorities of that city, and they so far approved his design as to nominate two physicians, Dr. Antonio Machado and Dr. Romay (who afterwards wrote his *éloge*), to be his assessors. On September 20th, 1816, he was conducted to the Hospital of St. John the Divine in Havana, and there he found a patient from yellow fever *in articulo mortis*. Valli watched the aspect of the sufferer—the black sanious blood oozing from his mouth and from other parts of his body; and, having felt his pulse, he withdrew. He returned next day to the bedside of the patient, now a corpse. Then, before proceeding to inoculate himself with the vomit and the bile, he put on the nightgown of the deceased, saturated as it was with perspiration, and rubbed it well over his back, breast, and abdomen. He had not long returned to his abode when the first symptoms of the peculiar malaise supervened. On the evening of the next day, September 21st, he sent for Dr. Romay, who found him pale as death, his strength gone, the life rapidly ebbing. He could pronounce only a few broken sentences, interrupted by long-drawn sighs. He said: "My fate is irrevocable; I am dying." Everything that his medical friends could do for him was done; but, after lingering in a comatose state till the third day from his seizure, he expired (September 24th). The Sociedad Económica of Havana, in grief and admiration for their guest, caused his portrait to be hung in the public library of the city, an honour up to that time accorded to but two members of the Society, and they also had inscribed on his tomb an epitaph, still read by the stranger in the cemetery of Havana, and of which the following is a translation:—"To God, the All-good and Almighty. Here lies Doctor Eusebio Valli, victim to his love for mankind; the Economic Society of Havana solicits for his memory the prayers of the pious. Anno Domini 1816." A descendant of Valli's, the Cavaliere Giuseppe Valli, advocate, has recently been at pains to collect all the papers and documents relating to his illustrious kinsman, and to weave them into a suitable memoir—mainly by the help of Spanish and other foreign coadjutors, his compatriots, by their neglect of the good and great physician's name and memory, having long incurred the reproach now launched at them by his latest biographer *Nemo propheta in patria sua!*

DISEASE IN PILLOW-STUFFING.

TRADE, we know, has always had its tricks, and with most of those who practise them it matters little whether they are or are not as harmless as they are profitable. If goods look well from the outside, and if they sell well, questions relating to their internal quality and their real value are too often settled by reference to that convenient rule of doubtful equity—*caveat emptor*. The principle of this adage was probably never quite a fair one. In all cases requiring technical knowledge, and their name is legion, it must allow the dealer a distinct advantage over the purchaser. We must remember also that the former may himself have been deceived. It is not he who is primarily responsible for the hidden faults of quality by which the most cautious buyer may be defrauded. It is the maker, who, with his eyes open, provides for a cheap market not only cheap and inferior but essentially bad material. Let us quote an example. A correspondent, whose letter we publish in another column, writes to expose the dangerous but common practice of stuffing pillows with rags and scraps of clothing of every variety and degree of dirtiness. He suggests with much force that some of those outbreaks of fever which arise from time to time in schools and families from no apparent source, domestic or external, may be traceable to this dishonest and filthy custom. The maxim wherein cheap and nasty are interchangeable terms, is fitly illustrated by our correspondent's description, and the remedy for the evil he denounces is largely in the hands of the public. In part, also, it is within the power of the sanitary authority. The agents of that body must, and constantly do, destroy what they can of unwholesome bedroom litter in houses where fever has been prevalent. If they will exert their discreetly unsparing zeal for cleanliness wherever, among rich or poor, the tradesman's heedless trick is planting the seeds of disease, we may expect to see some change for the better at least in one false custom of our time.

PROGRESS OF THE METROPOLITAN OPEN SPACE MOVEMENT.

BELIEVING as we do that if London is to remain at all tolerable as a place to live in for four or five millions of people open spaces must be not only kept but created, we notice with great satisfaction the progress of the scheme for the extension of Hampstead Heath. The adjoining parishes of Hampstead and St. Pancras have given or promised £50,000; the Metropolitan Board of Works have voted £152,500; and £50,000 will be forthcoming from the City of London Parochial Charities Fund under special Parliamentary powers obtained last year. As the amount required for purchasing and laying out the 265 acres is £305,000, it is necessary that £52,500 shall be given by the public. Already half of this sum has been advanced. The inhabitants of Hampstead and Highgate have subscribed liberally. The Duke of Westminster and the Duke of Bedford give each £3000. The Baroness Burdett Coutts is one of eight donors of £1000. It is inconceivable that this great scheme should fail for want of £25,000 more. London must not be behind the provinces in such matters. Another space of thirty acres for the public has been saved at Kilburn. It has been presented by the Ecclesiastical Commissioners to the Corporation of the City of London to be maintained as a recreation ground for ever. So far so good. But can nothing be done by legislation to restrict the wholesale building of superfluous houses and the multiplication "of long unlovely streets" where fields at present contrive to preserve a precarious existence? Babylon, with little more than a fourth of the population of London, consisted of nine-tenths of fields, parks, orchards, and gardens. London is very much the reverse of this, and it is high time that some restriction was put on the merciless invasion by bricks and mortar.

DAIRY PRODUCE.

THE commanding importance of all questions relating to our food supply lends special interest to an able article upon Dairy Produce which appears in the current number of the *Quarterly Review*. The writer shows by the collation of statistics that the dairy farmers of the United Kingdom had, ten years ago, suffered themselves to be sadly surpassed by foreign competitors, and that even at the present time their enterprise leaves much to be desired. Within the last decade, however, it would seem that considerable leeway has been made up; yet the extent to which this important industry is neglected among us may be collected from the fact that the proportion of milch cows in the British Isles is one cow to 9·2 per head of population. The corresponding proportion is one to 2·2 per head of population in Denmark, one to 3·1 in Sweden, one to 4·3 in the United States, and one to 5·2 in France. In fact, Great Britain takes her rank among the very poorest nations in respect of dairy stock. It is not surprising to learn that an industry so much neglected is often conducted on very unscientific methods. The ill success of many dairy farmers is by the *Quarterly* reviewer attributed to their ignorance—ignorance respecting which he remarks that it is "of the worst possible form: the lack of knowing their ignorance. So," he continues, in pursuance of this theme, "they continue to make butter in dairies that are close to muckhills or pig's courts, or that contain meat and other things which contaminate milk." So much for the dairy process; but the milk before it reaches the dairy is sometimes subjected to treatment of which he gives the following vivid and horrible description: "We have seen milk set for cream in the living room of an Irish cabin, full of peat smoke (which makes butter bitter), and redolent of the odours of cows, pigs, and poultry kept in the place; and we have seen it set in the bedroom where a whole family slept; in some cases, indeed, the milk is set under the beds. It is impossible that even tolerable butter can be made under such conditions, and as the small farmers of Ireland are so hospitable that they will entertain their domestic animals in their dwellings, and will raise cream there too, even when they have separate buildings better suited for both purposes, the establishment of butter factories in that country is the most hopeful means of speedy improvement in butter-making." That such treatment should impair the market value of the products is not only easily intelligible, but also matter for sincere congratulation. The unwary consumer, who is liable in this way to share the perils of a squalid habitation, is in any case much to be pitied, and it is a matter of great moment to him that some substantial inducement should be held out to the producer to avoid such insanitary processes in his manipulation of an article of food. It is not alone in the direction of cleanliness that the dairy farmer is now exhorted to mend his ways. Much has been done of late to accelerate and improve the process of extracting the cream from the milk by means of a centrifugal separator. Upon the whole, the *Quarterly* reviewer makes it abundantly plain that there is great room for improvement in the processes of the manufacture of milk products, and we cordially join in wishing all success to institutions like the Glasnevin Agricultural Training Institution near Dublin, and the Munster Dairy School near Cork, which are doing something at least, and something considerable, as we are fain to believe, towards promoting a general advance in these directions.

THE LATE DR. BERNARD KRAUS.

IN the death of Dr. Bernard Kraus on the 28th ult., at the age of fifty-nine, an energetic worker has been removed from medical journalism. He was one of the founders, and has been throughout the editor, of our contemporary, the *Allgemeine Wiener Medizinische Zeitung*, which is now in its thirty-third year, and which has throughout been characterised by independence and enterprise. Amongst the distinctive features of this journal have been the reports which are given every week of the clinics of the leading physicians and surgeons in the General Hospital, and the very extended and accurate reports of medical associations and congresses, at which Dr. Kraus himself was a constant attendant. In them the late editor took a great interest, and one of his special claims to recollection is his elaborate report on the London Hygienic Exhibition of 1884, made at the request of the Commune of Vienna. He was also author of a work on Medicine, which attained two editions. His fatal illness was short and unexpected. Symptoms of intestinal obstruction had been complained of for about a fortnight, and colotomy had to be performed on Oct. 26th. The cause of the obstruction proved to be chronic peritonitis.

TUBERCULOSIS, HUMAN AND BOVINE.

DR. A. G. YOUNG, Secretary to the Board of Health for the State of Maine, has prepared a report which is of considerable importance, as summarising the information which is available as to bovine tuberculosis and its relation to tubercle in man. He regards the etiological unity of animal and human tuberculosis as established, and appears inclined to adopt the views of Johne, to the effect that we can no longer doubt the possibility of the transmission of tuberculosis from animals to man through the consumption of flesh and milk of animals thus diseased. This is a subject which calls for even more extended observation than it has received; but in the meantime it is at least advisable not to use, for human food, the products of animals suffering from tuberculosis.

Digitized by Google

If there is substantial danger, it would appear to attach much more to milk than to the flesh of the implicated animals; for, though it cannot be asserted that the interior of ordinary joints is, during the process of cooking, raised to a temperature always sufficient to destroy the tubercle bacillus, yet the cooking of meat does tend materially to reduce the danger. If it were possible to induce people only to consume milk after it has been boiled or otherwise cooked, the danger with regard to that article of diet would be reduced to a minimum. Tuberculosis is by no means an uncommon disease in cows, and it has hitherto been felt that the condemnation of the meat of such animals must, in the interests of cheap food supplies, be limited to those instances where the disease is extensive in amount or in an advanced stage. With regard to milk, we must largely trust to the inspection of cowhouses and dairies, which has now been inaugurated in this country, and which will, we hope, before long, eliminate from amongst those cows which supply milk for human consumption any that are obviously suffering from tuberculosis.

LARGE LEGACIES TO HOSPITALS.

IT is gratifying to see indications that munificent charity is not dead yet, and that out of the heaps of money which accrue to some men, and which seem only fit for generous distribution in favour of less fortunate classes, splendid donations arise. We congratulate St. George's on being the object of such a well-deserved legacy—£100,000—the third of the sort, making it now one of our well-to-do hospitals, though still not independent of annual subscriptions to the amount of several thousand pounds. Let us hope that the turn of the other hospitals will come soon. Our great hospital system presupposes men like Guy, and cannot be maintained with petty subscriptions. One of our contemporaries takes the occasion of this legacy to indulge in some criticism of the expenses in wages and salaries in St. George's Hospital, and asks if £7440 is not a large sum to pay in wages and salaries for "so small a hospital." The criticism will no doubt be considered by the authorities of the hospital. Meantime, it is only fair to say that St. George's is not a small hospital; but that on the Hospital Sunday list it comes next in number of beds to St. Thomas's, and that it compares favourably even with the London Hospital in the cost of mere management.

ANTIPYRIN IN SEA-SICKNESS.

OUR Paris correspondent writes:—"The Société de Biologie has devoted part of its last two sittings to the discussion of the different means recommended for the relief of sea-sickness. A note was presented by M. Hantz on the best way of administering cocaine, and received without any expression of opinion. M. Dupuy said that sea-sickness was more severely experienced by dyspeptic subjects, and particularly those who had dilatation of the stomach. In eleven cases he had given antipyrin in doses of from two to three grammes for a few days before embarking, and the patients had all informed him that they had been free from sickness. M. Dastre said he had instituted a series of experiments upon animals, imitating as closely as possible the movements of 'pitching' and 'rolling.' He had found that there was an incredible displacement of the abdominal viscera, which strike against the diaphragm and cause the gastric uneasiness. The body struggles with these displacements by means of muscular contractions, and the respiratory rhythm accommodates itself to them. Professor Brown-Séquard remarked that this theory of visceral displacement was very old, and one which he had been able to verify in his frequent passages across the Atlantic. It was evidently the view entertained by Wollaston, who recommended Arago to place a pad over his stomach when he crossed the Channel. M. Maurel had no doubt as to the influence of the stomach, but thought the cerebral shock also played a part in the determination of the symptoms, inasmuch as the sickness always occurs when the boat is going down, never when it is being lifted up. The best preventive was lying on the back. Beyond the statement that sea-sickness is associated with dilatation of the stomach, and the hope held out by M. Dupuy that in antipyrin we now possess a remedy for it, there was nothing new in the views expressed by the different speakers. I have referred, however, at some length to the subject, because my own seafaring experience has been somewhat extensive, extending over intervals during the last fifteen years, and including some kind of trial of every new drug recommended. Until a month ago the plan I always recommended was to take bromide for some days before going on board, and, if discomfort was felt notwithstanding, the dorsal decubitus was to be adopted. This, together with champagne, is generally what the Transatlantic captains advise. In a recent trip to New York I tried two other remedies. The surgeon of the ship recommended me tincture of capsicum, and I had also taken a supply of antipyrin. As far as one case goes, the result of the antipyrin was most satisfactory, and I can to this extent endorse the experience of M. Dupuy. The capsicum was also serviceable as a palliative, for several persons who had taken it continued to ask for it, but it did not arrest the sickness like antipyrin. A fellow passenger who suffered from dilatation of the stomach with *clapotement* was not sick at all."

PUBLIC HEALTH IN VICTORIA.

FROM the annual report recently issued by the Central Board of Health of Victoria, it is evident that useful work is in progress for the promotion of public health in the colony. The township of Elmore is especially referred to as needing active supervision; it is said to be in a discreditable state, and to favour the spread of such diseases as enteric fever. When this is the case as regards any town, it is quite evident that there is fault somewhere; for the conditions favouring that disease are, above all others, essentially removable. First it is the duty of the sanitary officials to point out where the mischief lies, and to indicate the remedies needed, and then the authority themselves have responsibility for acting. Action is about to be taken to secure proper control of dairies and slaughtering places, and an effort to deal with the failure which has heretofore taken place is to be made by the issue of stringent instructions for the local officials. Some of the health officers are at present miserably remunerated, and those who are responsible for this must also in large measure be held responsible for the unhealthiness and death which result from a failure to secure proper supervision of the conditions under which the people live; for it is well known in every branch of life that the amount of work which can properly be expected of a paid official is indicated by the remuneration attached to his office.

EFFECT OF FARADISATION ON URINARY NITROGEN.

DR. P. A. VALTER has experimented on three patients suffering from chronic hepatic disease by faradising the skin over the region of the liver twice a day for some days, and estimating the urea and other nitrogenous compounds excreted in the urine before and during the faradisation, the diet being alike all through the observations. The conclusion he arrived at was that faradisation has some trifling effect on the excretion of nitrogenous matter by the kidneys, this being slightly increased.

THE MIDDLESEX AND HERTS COMBINED SANITARY DISTRICTS.

THE difficulties of medical officers of health are well illustrated by the event which has followed a recent action of the Barnet Rural Sanitary Authority. This board, anticipating some alteration in their district, determined to reappoint Dr. C. E. Saunders as medical officer of health for one year instead of for three years, as determined upon in the other districts of the combination. The Local Government Board, having endeavoured to induce the Barnet authority to reconsider this decision, finally assented, but thereupon informed the other authorities that they must separately appoint Dr. Saunders, there being no provision in the order for the continuance of the combination hitherto existing after the secession of one of the authorities named therein, and because much delay would occur before the necessary steps could be taken for the constitution of a fresh combination. It is a distinct misfortune that this combination has ceased to exist, and it certainly is very much to be regretted that the nature of the order should require this step to be taken. Dr. Saunders has rendered considerable service to the combined district, and the public would be sufferers if any circumstance should tend to break his continuity of office. As a matter of fact, he has, we believe, been re-elected for each district separately, but events such as this have a disturbing influence, and are calculated to depreciate the public health service in the opinion of the profession. The duties and responsibilities of a medical officer of health are sufficiently onerous without his being subjected to vexations of this kind.

PREVENTION OF INFECTIOUS DISEASE.

A CORRESPONDENT, writing to one of our daily contemporaries, states that he has often seen clothing destined for the use of Government servants and for those in Her Majesty's naval and military services being prepared in the same room where lay a child stricken with scarlet fever, and on one occasion he found thousands of circulars being folded by the desquamating hands of a child who had suffered from that complaint. He calls attention to the work of the Westminster Sanitary Aid Association, where a few ladies have arranged to send a "visiting woman" to all cases of scarlet fever notified to them by medical men, and he speaks of the success which has attended these efforts in inducing parents to send their children to hospital. Where due discretion is used, this method is calculated to prove of great value in checking the spread of contagious disease, and might well be adopted in other districts.

ASSURANCE FRAUDS.

THE recent disclosures in connexion with various assurance frauds are rather disquieting, since they show the comparative ease with which certain needy members of the medical profession may be induced to take an active share in a dishonest proceeding. The now famous Von Scheurer fraud would have been an impossibility but for the active co-operation of a French medical man, who supplied, at the moment when he was wanted, a patient dying of consumption, who could be taken charge of and buried under the name of Von Scheurer. Of the unsavoury ramifications of the case it is needless to speak; they belong rather to courts of law than to us; but we cannot pass over in silence a case which so strongly affects professional credit for truth and honesty of purpose. Assurance companies repose great confidence in the skill and probity of medical men; they are consulted as to the value of the risk incurred in each individual case, and their reports are justly considered as being confidential and faithful records of the results of their observations. They are appealed to once more when a claim is made, and again, by simple statement of fact, they give information which ordinarily tends only to the confirmation of the validity of the claim, but now and then they may give some unconscious word of warning which helps to detect an attempted fraud. The value of the information thus given, and its importance to the companies by whom medical referees are employed, should render them doubly jealous of any act which must tend to shake the feeling of unquestioning confidence hitherto reposed in them. In every calling there are unworthy members, but their proceedings, such as those recently brought prominently before the public in these assurance frauds, while they call for condemnation from all honest men, must rouse the strongest indignation in those whose good name is likely to be affected by the dishonesty of members of their own profession.

THE NATURE OF TETANUS.

DR. SHAKESPEARE, pathologist to the Philadelphia Hospital, read a paper upon Tetanus before the Section of Pathology at the International Congress, in which he related a series of experiments consisting in inoculations of rabbits with material obtained from the medulla and spinal cord of a horse or a mule which had died of traumatic tetanus. The inoculations were based on the methods adopted by Pasteur in rabies, and included injections beneath the cerebral dura mater, as well as subcutaneous and intermuscular injections. He concluded from these researches that traumatic tetanus of the horse and mule is sometimes, if not always, an infectious disease, transmissible to other animals, and therefore possibly to man; and that the virus, elaborated and multiplied during the progress of the disease, is capable of reproducing the disease in other animals by inoculation beneath the dura mater. The virus is contained in the medulla and spinal marrow, and, like that of rabies, is capable of attenuation by exposure to dry air at a temperature of summer heat. It also resembles the rabic virus in producing more intense effects when inserted beneath the cerebral dura mater than when injected subcutaneously or between muscles. Dr. Shakespeare reserved conclusions as to the prophylactic effect of inoculations of the attenuated virus, and pointed out that his results, in connexion with those of Nicolayer, Rosenbach, and others, suggested forcibly the dependence of traumatic tetanus, both in animals and man, upon the action of a specific infectious virus, and the probability that man may acquire the disease from animals—notably the horse.

CHOLERA IN SOUTHERN EUROPE.

IT is now some time since regular returns were received as to cholera either in Sicily or in Malta. As regards Messina, there was still a daily cholera mortality up to the close of the first week of October, fifty-five deaths occurring during the week, but only five of them took place during the last two days of that period; and since then no news has been received. It may therefore be hoped that the epidemic as such is at an end, and that the authorities will utilise the coming winter in taking such action as shall be necessary to prevent any recurrence of cholera next summer. As regards Malta, no daily bulletin has now been issued for over a month; but this does not mean that the epidemic has ceased, for during several of the past four weeks the weekly record of deaths has reached, or even exceeded, a total of forty. But during the last fortnight a distinct diminution in the number of fatal attacks set in, and it is sincerely to be hoped that those who are responsible for the sanitary administration of the island will find themselves soon free to decide whether they had better devote their

Digitized by Google

energies to the development of a quarantine system which has utterly failed them during the past year, or whether they should not consent to learn, as the result of experience derived from the differing incidence of the disease on their healthy and unhealthy areas, that the surest method of prevention is not to close their doors against that which can certainly make its way through, but rather so to improve the sanitary state of the island that any imported infection will fail to find in their midst such filth conditions as are essential to its development and spread.

BIOLOGICAL WORK OF THE SCOTTISH MARINE STATION.

THE fourth part of the Journal of the Scottish Meteorological Society contains a paper by J. T. Cunningham, giving an account of the work done during the past three years in the Scottish Marine Station. A portion of this work was done in the Firth of Clyde, in the vessel appropriately named the *Ark*, and part in the *Medusa*, at Granton, Millport, and elsewhere. The results are highly satisfactory. Mr. Henderson has discovered forty-four new invertebrates not previously known to occur in the Firth of Forth, and one which had not previously been found in British waters. Mr. Henderson also, in conjunction with the Rev. Canon Norman and Mr. John Murray, issued a list of the Decapodous and Schizopodous Crustacea. Mr. Cunningham himself has paid much attention to the anatomy and histology of the Chætopoda, and also to the reproduction and development of the fishes of the Firth of Forth, especially of the hag-fish. He has likewise obtained and published much information of a practical kind concerning the herring fishery, and made experiments on the spatting of oysters. Researches in marine botany have been carried on at Granton by Mr. John Rattray. A list of the papers published is given. Altogether, the results of the three years' work have been very satisfactory indeed. Many naturalists have availed themselves of the opportunities here afforded them for original work for periods of varying duration.

THE SPREAD OF LEPROSY.

THE question raised by Archdeacon Wright in the columns of *The Times* of Monday last is one of considerable importance, and quite worthy of the attention which our contemporary bestowed upon it. At the same time it may be hoped that it will not lead to any attempts at legislation by panic. To the question, Is leprosy increasing in this country? no doubt an affirmative reply would be the correct one. But that such an increase depended on contagion could not be answered in so positive a manner. For it is now fairly well established that as regards contagiousness leprosy stands in the category of such diseases as syphilis and tuberculosis, which are transmissible for the most part only by inoculation. The apparent increase of leprosy in modern Europe is not due to contagion, but to the vastly improved facilities of human intercourse with foreign countries. For, apart from a few cases of the inherited disease, leprosy, in this country at least, is only met with amongst those who have contracted it in centres where it is indigenous. The recent reply of the College of Physicians to the Colonial Office indicated to what extent the State might legitimately interfere in infected districts; and the suggestion of the College that leper asylums might well be founded and maintained by the State meets the case of our colonies. The further suggestion made in *The Times* as to registration is one which cannot be carried out until notification of infectious disease is made compulsory, however desirable it may be in theory. We would, however, emphasise the importance of further investigation into the nature of the disease as a duty devolving upon the Government of an empire which contains so many subjects who are afflicted with it; and in this, unfortunately, England does not appear to advantage in comparison with Norway. Perhaps now that public attention has been called to the matter, the Government will once more seek the aid of the College of Physicians to carry out such an investigation.

HEALTH OF THE CROWN PRINCE.

WE learn by telegram from San Remo that H.I.H. the Crown Prince was progressing satisfactorily until a few days ago, when a new growth was observed lower down in the throat. This growth, we are informed, looks malignant, but of course it may only be inflammatory. A portion of it will probably be removed and sent to Professor Virchow for examination. A later telegram announces that, owing to slight œdema of the orifice of the larynx, no laryngoscopic operation can be undertaken at present.

ORGANISED INQUIRY CONCERNING ILLICIT PRACTICE IN BELGIUM.

THE Belgian Medical Federation decided at its recent annual meeting to endeavour to obtain as much information as possible concerning infractions of the laws protecting medical men by illegal practice, whether by pharmacists or by other unqualified persons. The inquiry, which it is proposed to extend over a couple of years, is to be entrusted to the various local medical associations. These will doubtless accumulate an immense mass of documentary matter, which will be submitted to a central committee for examination and analysis. When this committee has achieved its task, it is hoped that so strong a case may be made out for more stringent legislation that the Chambers will accede to the almost universal demand amongst medical practitioners for more adequate legislative protection. It was pointed out during the discussion at the meeting of the Federation that great care would have to be exercised in dealing with the information obtained so as to avoid publishing the names of informants. The Antwerp Medical Society has, it seems, got itself into considerable trouble through taking up a case of illicit practice, of which information had been given by a person who thought it his duty to bring the circumstances before the Society, but who by no means relished seeing his name brought into a controversy which was subsequently carried on in the political newspapers on the subject, comments being, of course, made which were anything but complimentary to him. Medical men will, of course, refuse information to the associations unless they have a guarantee that this kind of thing is out of the question and that their communications will be treated as confidential. An amusing instance of evasion of the medical laws was cited by M. Kops, where a gentleman who took to doctoring people asked for no money payment, but requested a licence to shoot over his patient's estate!

GERMAN ENTRANCE EXAMINATION FOR MEDICAL STUDENTS.

AN important alteration is proposed in Berlin regarding the qualification for admission to the University of medical students. Hitherto all have had to pass the *abiturienten* or maturity examination at a *Gymnasium* or classical school, so that every German medical student has been obliged to prove an acquaintance with Greek. Now, however, the authorities have decided to admit after Easter, 1888, students who have passed the final or *abiturienten* examination in the *Real-Gymnasia* or non-classical schools. In these, Latin is of course taught, but not Greek. They correspond, in fact, to the "modern" or "civil and military" departments of our own public schools.

TREATMENT OF GLAUCOMA IN SPAIN.

DR. OSIO, the eminent Madrid ophthalmic surgeon, communicates to the leading Spanish medical journal an article on glaucoma, in which he urges his medical brethren most forcibly to pay sufficient attention to eye diseases so as to diagnose this formidable malady, which is, he says, "mathematically curable" by operation if taken in time. He draws a graphic but mournful picture of a patient, in whom this affection has commenced, applying to a practitioner, who orders leeches, and then, when the severe pains come on, gives hypodermic injections of morphia and prescribes the inevitable bromide of potassium, and, above all, unconscious of or indifferent to the universally admitted fact that atropine favours the development of glaucoma, instils drops of liquor atropiæ. Besides all this, perhaps he tries insufflations of calomel and drops of nitrate of silver or borate of soda. It is a wonder, Dr. Osio thinks, that eyes treated thus do not burst.

THE ANATOMICAL SOCIETY.

AT the next meeting, to be held on Tuesday, Nov. 22nd, at University College, at 5 P.M., the following papers are to be read:—Sir William Turner, (1) "Variations in the Hippocampus Major and Eminentia Collateralis," by Robert Howden, and (2) "A Metallic Body in the Spinal Canal," by David Hepburn. (3) "Minute Anatomy of Clarke's Column in the Spinal Cord of Man, the Monkey, and the Dog," by Dr. Mott. (4) "The Arteries at the Base of the Brain," by Professor Bertram C. A. Windle. (5) "Note on the Functions of the Sinuses of Valsalva and Auricular Appendices, with some remarks on the Mechanism of the Heart and Pulse," by Mayo Collier. Various specimens and methods will also be shown and demonstrated. This youthful Society gives promise of a useful and vigorous career.

TUBERCULAR ULCERATION OF THE TONGUE.

DR. L. V. ORLOFF, of the Princess Helena Pavlovna Clinical Institute, gives an account in a St. Petersburg medical journal of a case of tubercular ulceration of the tongue, the nature of which, though there were slight signs of pulmonary phthisis, was definitely decided by microscopical and bacteriological examination. The importance of this latter means of diagnosis is pointed out by Dr. Orloff. Tubercular ulceration of the tongue, when primary, as it sometimes is, might in this way, if diagnosed and treated, perhaps be prevented from being followed up by the pulmonary affection. Some experiments were made in order to test the possibility of direct communicability by inoculation of rabbits' tongues with the secretion from the ulcer, but only negative results were obtained.

FOREIGN UNIVERSITY INTELLIGENCE.

Bologna.—Dr. Pietro Albertoni, Professor of Materia Medica in Parma, has been appointed to the Professorship of Physiology.

Göttingen.—Professor H. Schwartz, Director of the Obstetric Clinic, has announced his intention of retiring at the end of the winter session.

Messina.—Dr. Francisco Coppola has been appointed Professor Extraordinary of Materia Medica.

Naples.—Dr. Luciano Armani, Extraordinary Professor of Pathological Histology, has been promoted to the rank of Professor.

Prague (German University).—Dr. Siegmund Mayer has been raised to the rank of Professor of Histology.

Santiago (Chili).—Dr. Landwehr, Assistant in the Physiological Institute (Department of Medical Chemistry), Würzburg, has been appointed to the Professorship of Physiology.

SPEAKING at Portsmouth, on the 3rd inst., on the abolition of the Contagious Diseases Acts, Sir George Willes, Commander-in-Chief at that port, stated that a disgraceful condition of things had been the result of the abolition. It was, he remarked, no use to hope to get the Acts passed again; but matters would get worse and worse, so that it was frightful to contemplate what the condition of things would be ten years hence.

THE *Gazette* of Tuesday announces that the Queen has been pleased by warrant under Her Majesty's Royal sign manual, to reappoint Sir Thomas Jamieson Boyd, Knight, to be Chairman of the Fishery Board for Scotland; and James Cæsar Ewart, M.D., Regius Professor of Natural History in the University of Edinburgh, to be a member of the said Board.

DEPUTATIONS from the Association of Fellows and the Association of Members of the Royal College of Surgeons will to-day (Friday) be received by the Lord President of the Council, and will lay before him their reasons for opposing the Supplemental Charter sought by the Council of the College.

WE beg to direct the attention of our readers to the exhibitions at Epsom College to be competed for next month. The successful candidates, who must be the sons of medical men, receive board and a first-class education for thirty guineas a year. Any detailed information will be given by the Rev. the Master, The College, Epsom.

THERE is no diminution in the epidemic of measles at Derby, and the sanitary authority have issued circulars to the medical men practising in the town to report cases coming under their notice, in compliance with the local Act for the Compulsory Notification of Infectious Diseases.

THE Corporation of London on Tuesday decided upon giving such Parliamentary notices as will enable the Fire Inquest Bill to be extended to the whole of the metropolis if necessary.

BY the initiative of some of the senior students, a society has been instituted at the University of Aberdeen under the title of the Students' Medical Association.

AMONG the recent promotions to the rank of Chevalier of the Order of Leopold is that of the able editor of our Belgian contemporary, *Le Scalpel*, Dr. A. Festiaerts.

THE Morton Lecture is to be delivered by Sir James Paget, Bart., F.R.S., at the Royal College of Surgeons, at 3 P.M. to-day (Friday).

MR. JAMES TEEVAN, F.R.C.S., who ten years ago was a well-known West-end surgeon, died last week at Bath.

QUEEN'S COLLEGE, BELFAST.—The following are the Scholarships in Medicine for 1887-88:—Anatomy and Physiology: J. M. Hall. Therapeutics and Pathology: R. W. Haslett, B.A.; Robert Wilson, a prize. Third Year Medicine: James M'Connell, B.A. Second Year Medicine: H. T. Heron, B.A.; J. A. Browne, B.A.; J. S. Morrow, B.A., a prize. First Year Medicine: Robert Montgomery, literary; T. B. Pedlow, B.A., science. Dunville Studentship: J. M. Hall; H. L. Atkinson, B.A., a prize. Andrews Studentship: Alexander Jamison, B.A.; C. E. Shaw, M.A., M.D., a prize; J. S. B. Larmour, B.A., a prize. Porter Scholarship: W. W. Haslett; J. A. Stewart, a prize. Sullivan Scholarship: James Robinson. Sir Hercules Pakenham Scholarship: J. C. Rowan.

SCOTCH INTRODUCTORY LECTURES.

UNIVERSITY OF GLASGOW.

THE winter session of the medical department of the University of Glasgow was opened on the 25th ult. The introductory address was delivered by Professor P. A. SIMPSON, who, after a brief glance at the changes that have occurred in the University since 1874, when he last addressed some words of welcome and encouragement to the students at the commencement of a winter session, proceeded to discuss at length the subject of the various channels which are open to medical graduates when they leave their university. With regard to emoluments, their profession was not, he said, one in which the realisation of a fortune was to be looked for. A fair competency was all that could be expected. The prize to be won in the medical calling did not consist of bank-notes, but in the inward satisfaction of having to some extent contributed to the extension of medical knowledge, as well as to the alleviation of human suffering. The navy offered for a young medical practitioner a career which befitted an educated gentleman. Prof. Simpson then strongly deprecated the abolition of "relative rank" in the Army Medical Staff, and advised his hearers not at present to join that branch of the services. Dealing with the question of the proportion of medical men to the population, he dwelt upon the large increase that had taken place in the number of practitioners in this country in recent years, and suggested the colonies as offering to the young medical graduate in quest of a suitable locality for his future home a sphere of usefulness much larger than was at the present time to be found at home. He was very far from being in favour of a medical career for women, holding as he did that by frame, temperament, and mental constitution woman was not well adapted for medical, far less for surgical practice; but he did not think that the members of their profession should do more than exercise a private influence against the destination of young women to the medical profession. Medical practitioners had ample opportunities of supplying information concerning the nature of a medical student's career, the difficulties and dangers of the profession, and so of tempering this unfortunate enthusiasm. But it was never, he thought, the office of their profession to lead the van of any crusade against the admission of women into their ranks. Such opposition was sure to be decried as akin to trades unionism, and it was difficult to refute the charge, however untrue. They might honestly say that the opposition of their profession to the admission of women was disinterested, and was solely to prevent injudicious women from embarking on a course which must prove injurious to them. As to the wisdom or folly of women adopting medicine as a profession, let women themselves be the judges. So long as they contented themselves with schools of their own, and desisted from clamouring for that abomination—viz., mixed classes,—they had no ground for complaint, but should rather wish them god-speed.

ANDERSON'S COLLEGE.

DR. EBEN. DUNCAN, in his address, referred to the subject of the affiliation of the medical schools of the city, and said he saw no difficulty in devising a scheme which would safeguard the interests of the present professors of the University. Anderson's College would soon have new premises, and what could be more to the advantage of medical teaching, and tend more to the advancement of University interest, than the inclusion of Anderson's College as a college of the University and the recognition of its teachers as the professors? When they had the Royal Infirmary Medical School, a younger school with the great advantage of proximity to a great hospital, also quite willing to lend a helping hand, why should the University, admittedly short-handed in teaching powers and in class-rooms, refuse the assistance which the governors of that school were now offering? He had heard only one reason against it, and that reason was that the present University professors, with their endowments, their splended buildings, and the prestige of their positions, were afraid to be exposed to the chances of teaching with younger men, who would have nothing to attract but the energy and the ability with which they conducted their classes. For that reason, it was said, the professors would strenuously oppose any reform. But, in answer to any such opposition, might it not be justly argued that if, in spite of all the advantages which the senior professors in the College at Gilmore-hill would continue to possess, even after the affiliation of both Anderson's College and the Royal Infirmary School of Medicine, they could not retain their students, then it was certainly highly in the interest of the students and in that of the public that they should lose them. The only interest which the public or the Government could legitimately have was that the student and the University should get the benefit of the best brains of the best teachers. If they could induce the Government to combine the medical schools of Glasgow into an individual teaching faculty of medicine, with their advantages they should be able to place Glasgow in the foremost place, and not only maintain but increase the reputation of their country as a great seminary of medical science.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.

DR. NEWMAN, who delivered the introductory address at this institution, took as his subject the correlation of medical studies, especially in their relation to scientific study. The mutual relationship, he said, which existed between the different branches of medical education were very apt to be lost sight of, partly on account of the arrangement of the curriculum of the students. Their general education and part of their scientific education were separated from their medical studies by the artificial barrier of an examination. So also were their elementary studies, as distinguished from the more advanced. It was common, he said, in addresses such as that which he was offering to speak of medical science, but he wished to state that medicine was not a science. If placed among the sciences it would be among the very lowest, whereas among the arts it occupied a high position indeed. If they studied, and imagined that by doing so they were scientific men, they were greatly mistaken. Medicine was far too incomplete. There were no great laws which could apply to it. It occupied, to his mind, very much the same position that the chemistry of the alchemists did. It was destined, no doubt, at some time to occupy a place amongst the sciences, but at present it was in an undeveloped and embryonic state. But medicine rested upon a number of very important sciences, and it was apt, because these sciences assisted it, to be called itself a science. The great advantage that a student had from a scientific training was that, before he entered the medical profession, not only was he taught the effects of science, but he also learned the scientific method. In his study of medicine the student was to apply this method, and by so doing to endeavour to elevate his art into the position of a science. In closing, he asked the students to remember that whatever was a real advantage to themselves was a direct advantage to some of their fellow-men. On this point the medical profession might be said to differ from all other professions. The amount of true success depended on the motives with which they entered. To those who adopted medicine as a trade—and it was the lowest of trades, for it trafficked on the ills of their fellow-men—it was neither satisfactory nor remunerative, although it might elevate them from a position of obscurity, and afford an opportunity of being associated with gentlemen. To those who entered it to study an interesting branch of human knowledge it opened a wide field for scientific inquiry. To those who pursued it with a desire to advance the healing art by exact and scientific methods, inspired with a desire to alleviate the sufferings of their fellow-men, it was a noble profession, and deserved well of all, since it was intended for the indiscriminate benefit of all.

PARKES MUSEUM.—The Right Hon. the Earl of Meath has consented to give the opening lecture of the forthcoming winter session at the Parkes Museum, Margaret-street, Regent-street, W., on Nov. 17th, at 5 P.M. His lordship has chosen for his subject "The Importance of Open Spaces." The winter programme of lectures is unusually full, and bids fair to be most attractive. Amongst the lectures we notice one by the chairman on "Smoke and Fog"; by Dr. Frank Payne on "Plagues, Ancient and Modern"; by Prof. E. M. Crookshank on "The Germ Theory"; and one by Mr. A. S. Murray on "The Physical Training of the Greeks and Romans."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5713 births and 3800 deaths were registered during the week ending November 5th. The annual rate of mortality in these towns, which had steadily increased in the preceding six weeks from 16·2 to 21·5, was last week 21·4. During the first five weeks of the current quarter the death-rate in these towns averaged 19·6 per 1000, and was 0·9 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·7 in Hull, 13·2 in Brighton, 14·9 in Leicester, and 16·2 in Huddersfield. The rates in the other towns ranged upwards to 27·6 in Oldham, 29·1 in Preston, 30·7 in Bolton, and 31·0 in Halifax. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 392 and 464 in the preceding two weeks, further rose last week to 466; they included 144 from scarlet fever, 77 from diarrhœa, 75 from measles, 60 from whooping-cough, 57 from "fever" (principally enteric), 32 from diphtheria, and 21 from small-pox. These zymotic diseases caused the lowest death-rates last week in Leicester, Hull, and Huddersfield; and the highest rates in Bolton, Preston, Oldham, and Sheffield. The greatest mortality from scarlet fever occurred in Norwich, Blackburn, Oldham, Birkenhead, Salford, and Preston; from measles in Birmingham, Blackburn, Bradford, Bolton, and Derby; and from "fever" in Derby and Sunderland. The 32 deaths from diphtheria in the twenty-eight towns included 19 in London and 3 in Manchester. Small-pox caused 21 deaths in Sheffield, but not one in London or any of the twenty-six other large provincial towns; the 13 cases of small-pox under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease showed a further slight increase upon recent weekly numbers. The number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 2692 at the end of the week. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 206 to 485, further rose last week to 506, and exceeded the corrected average by 115. The causes of 74, or 2·0 per cent., of the 3800 deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Sunderland, Preston, and in three other smaller towns. The largest proportions of uncertified deaths were recorded in Oldham, Leicester, Huddersfield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1 and 22·2 per 1000 in the preceding two weeks, declined again to 20·6 in the week ending Nov. 5th; this rate was 0·8 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·1 and 16·1 in Leith and Edinburgh, to 24·0 in Dundee, 25·9 in Perth, and 29·1 in Paisley. The 515 deaths in the eight towns last week showed a decline of 39 from the number returned in the preceding week, and included 26 which were referred to whooping-cough, 14 to scarlet fever, 8 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 6 to diphtheria, 6 to measles, and not one to small-pox; in all, 66 deaths resulted from these principal zymotic diseases, against 68 and 70 in the preceding two weeks. These 66 deaths were equal to an annual rate of 2·6 per 1000, which corresponded with the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 30, 16, and 26 in the preceding three weeks, were again 26 last week, of which 10 occurred in Glasgow, 4 in Greenock, 3 in Edinburgh, and 3 in Dundee. The deaths from scarlet fever further declined last week to 14, from 23, 22, and 19 in the preceding three weeks; 9 occurred in Glasgow, 4 in Dundee, and 2 in Edinburgh. The 8 deaths attributed to diarrhœa showed a further decline from recent weekly numbers, and included 5 in Glasgow and 2 in Edinburgh. The 6 deaths referred to "fever" corresponded with the number in the previous week; 3 were returned in Paisley and 2 in Edinburgh. Four of the 6 deaths from diphtheria were returned in Glasgow; and of the 6 fatal cases of measles, 2 occurred in Glasgow, 2 in Dundee, and 2 in Perth. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 87 to 124, further rose last week to 131, and exceeded by 13 the number returned in the corresponding week of last year. The causes of 57, or more than 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 24·1 and 32·1 per 1000 in the preceding two weeks, was 31·0 in the week ending November 5th. During the first five weeks of the current quarter the death-rate in the city averaged 27·7 per 1000, the mean rate during the same period being but 19·0 in London and 18·5 in Edinburgh. The 210 deaths in Dublin last week showed a decline of 7 from the number in the previous week; they included 19 which were referred to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 6 to measles, 5 to diarrhœa, 2 to whooping-cough, 1 to diphtheria, and not one to small-pox. Thus, the deaths resulting from these principal zymotic diseases, which had been 29 and 42 in the preceding two weeks, were 41 last week; they were equal to an annual rate of 6·1 per 1000, the rate from the same diseases being but 2·6 in London and 1·6 in Edinburgh. The fatal cases of scarlet fever, which had been 8 and 11 in the previous two weeks, further rose last week to 19; and the deaths referred to "fever" also showed an increase upon recent weekly numbers. The deaths from diarrhœa, measles, and whooping-cough showed, however, a decline. The deaths both of infants and of elderly persons exceeded the numbers returned in the previous week. Four inquest cases and 3 deaths from violence were registered; and 59, or considerably more than one-fourth, of the deaths occurred in public institutions. The causes of 32, or more than 15 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

"THE PRESYSTOLIC MURMUR, FALSELY SO CALLED."

To the Editors of THE LANCET.

SIRS,—I wish it were possible for me to notice in detail all the valuable communications which my humble paper has called forth, but I must confine myself to some, hoping so to select as to bring into consideration all the more important points.

Dr. Gairdner refers to a feature of the "auricular-systolic" murmur as having been overlooked by myself and others. The murmur, in his view, "may appear to be prolonged out of, or even quite through, the period of rest, being in this last case necessarily associated with a degree of the ventricular-diastolic murmur presently to be described. •Its essential character, however, is preserved in every case, as above defined, and as represented in the diagram." In this diagram (in "Clinical Medicine") the sounds are indicated by vertical lines, the murmur by shading which reaches from the second to the first without a break, though not evenly, for it is lower in the middle than at either end, mounting steeply towards the first sound. Thus we have a murmur which begins while the ventricle is in the undoubted act of opening, which can be made only by a current which sets inward, because there is none in the other direction, and yet this is continuous with the murmur the auricular source of which is disputed. Dr. Gairdner does not see how this observation can be reconciled with the view I have presented. Neither do I. If the so-called presystolic murmur is continuous without break, pause, or change of tone, is all of a piece, with that which begins immediately after the second sound, then the two are one, both are auricular-systolic, and my contention falls to the ground. But I have never recognised such a murmur. I have heard not infrequently a soft apex murmur in the diastole close upon the second sound, the old mitral diastolic, and I have known this to be followed by the characteristic note of the so-called presystolic, but never without a break. Dr. Gairdner suggests to me, as the only course open, to explain the

Digitized by Google

supposed single murmur as two; this suggestion I adopt, not with any intention of warping facts to suit a controversial purpose, but as representing the evidence of my own ears. I may be wrong, and am the more likely to be so since I am opposed to an auscultator of Dr. Gairdner's proved skill and experience; but my conviction is as I have stated it. I have heard, not often, for such cases are rare, but as I have thought clearly, the old mitral diastolic followed after an interval by the so-called presystolic; but the murmurs to my ear have always been separate in time and different in character. Dr. Gairdner, indeed, "is not indisposed to admit with Dr. Balfour that the diastolic element of this murmur is softer, as a rule, than the presystolic; and that it may also occur in some cases where the latter is indistinct or perhaps even absent."[1] Dr. Gairdner admits the existence of these cases "with some difficulty," for to admit them is to admit the old mitral diastolic murmur and mark a distinction between it and the so-called presystolic. The difference between Dr. Gairdner and myself on this point is but of small, and I hope lessening, dimensions; it is nothing more than the halt of a stammerer, or a hyphen between two syllables; but it implies much.

To take another particular which relates to the continuity of murmurs. In presenting the general conception of the "presystolic" tune, and while disputing its meaning describing the sounds involved according to common acceptance, and as I thought correctly, I spoke of the so-called presystolic murmur as "running up to the systole, as being united to the systolic sound without separation, and as being *inseparably blended with the systolic murmur, should there be one.*" I was here referring, not especially to Dr. Gairdner, but to the presystolic creed as generally held. How common a clinical experience is it for a murmur which has been under discussion as to whether presystolic or systolic to be satisfactorily settled as a presystolic running into a systolic. How often it happens (and here I speak for myself) that a so-called presystolic and an undoubted systolic are associated, variously interchanging, sometimes more of the one, sometimes more of the other, but never separated by any definite demarcation. I need scarcely recur to my purpose in insisting on this fusion in repute and in fact. The argument is simple. I say it is impossible for an auricular systolic to mix with a ventricular systolic, for the blood is going different ways. The so-called presystolic thus mixes, therefore it is not auricular. Dr. Gairdner here protests against admitting this mixture of murmurs. But in the oft-quoted "Clinical Medicine" (p. 557), in speaking of the various combinations of murmurs, he says: "It is not unusual to have an auricular systolic and a ventricular systolic murmur combined as in the figure; *they may even appear to be so combined as to constitute but one murmur:* you will commonly, however, be able to detect the first sound in the middle of this murmur, splitting it, as it were, into two." (The italics are mine.) The diagram represents the supposed two murmurs by continuous shading, through the densest part of which a line passes to indicate the position of the first sound, but no interval is represented. Again, Dr. Gairdner says, in speaking of combinations of murmurs, "The greatest degree of difficulty" in distinguishing them "is when the normal sound is merged in the murmur, as it often is when an auricular-systolic and a ventricular-systolic are combined," and then Dr. Gairdner goes on to explain that the distinction rests on a difference of tone between the former and latter part of the combination, the former represented by repeated *r's*, the latter by repeated *f's*. Dr. Balfour also gives a figure[2] similarly constructed to Dr. Gairdner's, which is designed to show "a diastolic murmur separated from the succeeding presystolic murmur by a pause, while *the auricular-systolic murmur passes directly into a ventricular-systolic one.*" (The italics are mine.) The diagram shows a space between the shadows which represent the diastolic and the presystolic murmurs, while the presystolic shadow is continued into the following systolic, though a line through its densest part marks the position of the first sound. I quote these descriptions of Dr. Gairdner and Dr. Balfour in the belief that they are absolutely correct as representing what is heard, apart from any differences of opinion as to what the murmurs should be called, and how explained. What I doubt is not whether the murmurs so mix, but whether the two which so mix are made in opposite directions. But now Dr. Gairdner insists with more emphasis on the separation of these murmurs than on their union. This involves, as will be seen, an important admission. "I have been at the utmost pains to show," says Dr. Gairdner, "that these two murmurs are never thus inseparably blended, that they always preserve their exact separate rhythm, and are sharply demarcated from one another, either by the first sound remaining clear and definite (as it usually does) between the two, or by an abrupt change in the character of the murmur itself, marking, as it were, an interval between them (though the interval may be too brief to appear *soundless* to the listening ear)." Even now we have not got to an interval, but only to an interval "as it were." But at least there must be a sharp demarcation of some sort, in the absence of which I gather that Dr. Gairdner would not allow the murmurs to be of opposite kinds. I can only rejoice that so great an authority should concur with me on so important a point as the necessary separation of an auricular-systolic from a ventricular-systolic murmur. I shall henceforth hold with increased tenacity to the belief that a murmur which runs into, or coalesces with, an undoubted systolic is not presystolic, but only falsely so called. We have here a test which will, I think, be decisive against many murmurs which have hitherto passed as auricular.

I will take Dr. Balfour's letter next, for part of it is answered by what I have already said in reply to Dr. Gairdner. To take Dr. Balfour's points in their order: He thinks it "remarkable that the ventricle should be supposed capable of producing this loud rough murmur at the first beginning of its systole, when it is acknowledged that as this systole nears its acme and gains in force the murmur grows less and actually becomes soft and blowing." I thought the murmur, as a rule, began feebly and gathered strength as it went on—a mode of proceeding which might be expected, presuming it to be of ventricular origin. Again, in referring to the time of the mitral diastolic murmur, I had spoken of a period after the conclusion of the systole during which the ventricle "waits empty and still." This is not important for the purpose of the argument, but Dr. Balfour spies an error and quotes Hope to the effect that "the expansion of the ventricle immediately succeeds its active contraction," and, adds Dr. Balfour, "I know of no modern observations tending in the least degree to invalidate this statement." Let me refer Dr. Balfour to the well-known text-book of physiology by Dr. Michael Foster, fourth edition, pages 149 and 154, where he will find evidence that "the ventricle continues contracted after its contents have entirely left the cavity," and that the time for which it does so has been the subject of measurement. And now Dr. Balfour, by way of giving me the *coup de grace*, being already sore wounded, takes up anew a point which has already been dealt with by Dr. Gairdner. Says Dr. Balfour: "Dr. Dickinson objects to the term *continuous* being applied to the double murmur audible at the apex in many cases of mitral stenosis, and composed of the rough auricular-systolic murmur, immediately followed by the blowing ventricular-systolic murmur." Here I am a little misinterpreted. I do not object to—in fact, I commend—the use of the term *continuous* as applied to the so-called presystolic and the undoubted mitral regurgitant murmurs. I think the term represents the fact. What I do object to is the inference that of the two murmurs thus continuous, one goes one way and one another. This argument appears to have told, if I may judge by the efforts made to escape from it. Dr. Balfour explains: "The auricular-systolic murmur runs up to, and is continuous with, the ventricular-systolic (regurgitant) murmur, in the same sense of the word that the aortic-systolic murmur may be said to run up to and be continuous with the aortic diastolic (regurgitant) murmur, and when the systolic portion of this latter murmur is rough the analogy is very complete." Does Dr. Balfour really mean this? Does he ask us to believe that the so-called presystolic murmur is no more united with the undoubted systolic than are the opposed aortic murmurs with each other? Has Dr. Balfour never heard the double aortic murmur likened to the noise of a saw, or known it to be mistaken for the double rub of pericarditis? Has he ever heard the apex combinations in question so likened, or has it ever seemed to him to resemble the noise of pericarditis? Is it not going rather too far to say, as in the passage I have quoted, that the analogy between the murmurs in question is, in certain circumstances, "very complete." This appears to present a change of front; I welcome it as indicating a weakness of position. At any

[1] See foot-note on page 782. [2] Diseases of the Heart, p. 119.

Digitized by Google

rate, on this point we are agreed—if two apex murmurs are virtually inseparable, we are no longer to call one auricular and the other ventricular. Dr. Balfour tells us, in conclusion, "that it will be seen from the foregoing that" my "quarrel is with physiology and with facts, and not merely with opinions." I really do not see it "from the foregoing," which consists chiefly of what I have referred to; but when Dr. Balfour says I quarrel with physiology and facts, does he not really mean "with physiology and facts as interpreted by Dr. Balfour"? If he means this, and he cannot well mean otherwise, I am with him.

Dr. George Johnson points to the difference in conduction between the murmur of mitral constriction and that of acknowledged regurgitation as evidence that the currents which make them are in different directions; one murmur, as is well known, is nearly limited to the apex, the other is heard at the back. The fact has often presented itself to my mind, with this as possibly its explanation. The regurgitation with the so-called presystolic is through a small hole, and necessarily of small volume; it is not likely to carry its murmur so far as the copious gush which goes through the uncontracted opening. Dr. Johnson has satisfied himself that the murmur of mitral constriction precedes the impulse of the contracting ventricle, and is therefore presystolic in rhythm. I can say nothing to this, excepting that my observations have led me to a different conclusion. It has been objected, says Dr. Johnson, that "the auricular contraction would be insufficient to cause a murmur in a constricted mitral orifice." I never said so; on the contrary, I gave examples of murmurs thus produced. But I endorsed Dr. Barclay's words, that this force was insufficient to produce "one of the loudest and roughest murmurs ever heard in disease." This opinion I adhere to. It is true, as Dr. Shearar and Dr. Johnson say, that a considerable murmur like the *bruit de diable* in the neck may be made with little force or rapidity of current, but neither is the murmur connected with anything which suggests force to the touch; it is *vox et præterea nihil;* but the "presystolic" is associated with powerful movement, as the impulse and thrill testify. Where this murmur has been intense, I have sometimes been struck after death with the small amount of hypertrophy of the auricle; not what one would have expected had the murmur been auricular. I am aware, as Dr. Johnson has pointed out, that the cardiograph has been supposed to indicate that the first movement of the ventricle is coincident with auricular contraction; but the auricular part of the movement is small, probably inappreciable except by the machine, and not likely in any circumstances to be magnified into the long and rising impulse which keeps time with the "presystolic" murmur.

I had hoped to have replied separately, as their value demanded, to all the communications which have presented views contrary to my own; I regret that this has become impracticable, but I think I have omitted no essential objection. Neither need I refer in detail to those who have concurred with me, but will be content with acknowledging in general terms the important support I have received.

To conclude, let me hold up to view a common so-called presystolic murmur which begins gradually and ends abruptly, like something which expends its force against an obstacle, a steam-engine which rolls up against buffers. Its rumbling tune is all of one sort, and I presume that no one will now maintain that the beginning and the end of it belong to contrary murmurs. It is therefore all ventricular or all auricular. If auricular, what has become of the systole of the ventricle? The action of the heart, like the Government of the Queen, must be carried on. On the auricular theory there is no time for the ventricular contraction unless this laborious piece of work is comprised within the brief knock or snap which immediately follows the movement the nature of which is in question. This is short allowance. This snap is immediately or almost immediately followed by the second sound, with which the ventricular systole obviously terminates. Assuming, on the other hand, that the tangible impulse and rolling murmur are ventricular, how well the theory holds together. The idea of ventricular contraction suits the snap which comes at its end, presuming this to be made by the shutting of the mitral valve, together with tension of the chordæ tendineæ. That the short sharp sound is of this nature is borne out, as I think I have shown, by the post-mortem appearances; it must necessarily come at the end of the ventricular systole, because the flaps are rigid and must come together only slowly and when the ventricular walls are approximated. I therefore end as I began, with the belief that the so-called presystolic murmur is one of mitral regurgitation. Dr. Gairdner allows that there are mysteries about the "presystolic" murmur as he views it. From my point of view I see nothing mysterious about it.

If I have spoken emphatically, I trust I have said nothing to imply want of respect for the great authorities whose views I have presumed to criticise. If there is any truth in what I have urged, it must add value and permanence, because it supplies explanation, to the great clinical guide which we owe chiefly to Dr. Gairdner. The points of difference must be settled by further observation rather than by argument; this belief, at least, we may all share, and may agree to address a final appeal to the independence, experience, and wisdom of the future.

I am, Sirs, yours truly,

Chesterfield-street, W., Nov. 1887. W. HOWSHIP DICKINSON.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—This interesting question, which THE LANCET has put before the profession, will find many ready to accept the belief, upon mere analogy, that cancer is contagious. There are those who have been for years diligently searching for the germ which may have excited the cells of a part to such excessive abnormal action; and these observers have been at times ready to state that they had procured a distinctive organism. There is something so temptingly inviting in the idea that a cancer is a human oak-gall—that what the penetrating animal diplolepeis excites in the oak may possibly have its prototype in the ravages of some minute vegetable organism in man. Moreover, the growth excited by the bacillus of tubercle gives further support to such credence. I do not profess to approach the subject from any but a clinical aspect, and I can see that a mass of evidence must be collected before any true decision can be arrived at upon such data. Experiment affords a much more promising field. It has been tried, but with little success, owing probably to difficulty of proving a suitable nidus, and perhaps, too, from the inoculations having been made with the cell results rather than with the cell causes. This, however, I would suggest to such operators: that, as cancer is a disease of age, the oldest animals procurable would probably be its most ready recipients. Since THE LANCET put the question on Oct. 8th there have been three cases published in which cancer of the womb in the wife was associated with epithelioma of the penis in the husband. It is an interesting coincidence, but we have no evidence that the cancers were of the same type. If it were shown, for instance, that in the woman the growth was a colloid cancer of the body of the uterus, would that entirely invalidate the idea of contagion when the husband's growth is known to be epitheliomatous? We now, in explaining the well-recognised heredity of tubercle, are fain to believe that in a particular type of the human species Koch's bacillus finds a peculiarly appropriate soil. Will the individual and the part attacked explain the form of cancer? Besides the three cases referred to, one of your correspondents has put forward a case of cancer of the womb in the wife associated with epithelioma of the tongue in the husband. If, however, it may come about that some one germ may produce different forms of cancer in different individuals, modified also by the part attacked, then cases occurring in persons living together will become of great interest and importance, apart from direct inoculation.

The following curious instance of three different forms of cancer, occurring in three individuals living together in the same house, may some day receive an explanation other than that of mere coincidence. In 1881, and again in 1883, I operated on a gentleman suffering from rodent ulcer of the eyelid and forehead. He is still living, but with a return of the growth. In 1884 I operated on his wife for scirrhus of the breast; and during the past week a partner, who has always lived in the same house with them, has come under my care with epithelioma of the tongue. I would not suggest that there is of necessity anything more than accidental association between these cases, but the coincidence is the more interesting in that there is no blood relationship between them. Before one has learnt to attribute the ravages of

Digitized by Google

cancer to the introduction of some external virus, one must have regard to the more apparent contributaries to its outbreak; and if asked as to these, I should give, in order, age, syphilis, melancholia, gout.

I remain, Sirs, yours truly,

R. CLEMENT LUCAS, B.S. Lond., F.R.C.S.,
November, 1887. Senior Assistant Surgeon to Guy's Hospital.

To the Editors of THE LANCET.

SIRS,—The subject of the possible contagiousness of cancer has now been discussed in your columns for several weeks, but perhaps yet another illustration of its probable occasional conveyance from one individual to another may be worthy of mention.

Some few years ago I was consulted by a married man respecting an irregular nodule which had appeared beneath Poupart's ligament on one side. This growth gradually increased and extended itself upwards into the iliac fossa, developing into an ordinary malignant tumour. The patient died at a not very distant date. There was no disease of the penis. Some few weeks later the wife of this patient consulted me for uterine symptoms of some considerable duration, and on examination I found her to be affected with extensive cancerous disease of the os uteri and vagina. She also died in due course. I had at the time, and have now, little doubt that the case was one of infection, and that the malignant groin tumour of the husband was due to absorption of the discharge from the wife's uterus; but whether through a temporary abrasion or through unbroken skin I could not tell. Such discharge doubtless contains the freed nuclei or nucleoli of the cast-off cells, and it is quite reasonable to suppose that these minute bodies may be capable of absorption under favourable circumstances, and so induce new growth in the spot where arrested.

In this respect this case would differ from those in which secondary cancer is implanted, or communicated by abiding contact with adjacent tissue, examples of which latter are occasionally seen in cancer of the peritoneum.

I am, Sirs, yours obediently,

Norwich, Nov. 8th, 1887. PETER EADE, M.D. &c.

REFORM AT THE COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—The crowded state of the general meeting held on the 3rd inst. is one proof the more, if proof were needed, that the medical profession is fully alive to the momentous issues at stake between the Council and the great mass of the corporation of the College. The Members are showing that they feel the responsibility of their position as constituent parts of "*one body politic and corporate*." Such a spectacle of overflowing benches can never have been even dreamt of four years ago; and yet it is less than that space of time since the pebble was first cast whose ever-widening rings of undulation have spread to the outer boundaries of this mighty sea. To yourselves the Members of the College owe a debt of gratitude for this encouraging demonstration, for without the aid of the medical press our own toil and our own efforts must have taken many a weary year in bearing fruit.

There were two special points of interests in last week's meeting that call for notice. The first, the noteworthy fact that one member of the Council, Mr. Willett, broke the accustomed statuesque repose of that group of silent figures by holding up his hand in favour of the first resolution. The second, that Sir Joseph Lister destroyed the illusion of the theatrical *mise-en-scène*, by addressing himself to the meeting; for hitherto the President alone had condescended to parley with us.

If anything, the action of the Council was more unconstitutional than usual, for, having called a general meeting of the *corporation* (we persist in calling the College by its chartered name) to receive, and presumably to discuss, its annual report, it refused to submit to the meeting the resolution sent in duly by Mr. Pollock, and maimed that of Mr. Tweedy. Moreover, the Chairman of the meeting (for every such meeting *must* have a chairman) declined to transmit a resolution carried at the meeting to the authorities to whom he was bidden by the meeting so to do. This was but another instance of the weakness of the tactics chosen by that august body, the Council of the Royal College of Surgeons of England. With a bad hand to play, it always selects the most disastrous cards to follow with, and seems blind to the consequences of insisting that clubs are trumps, whatever the turn-up card may have so far forgotten itself as to be.

We pass over for the present the magnificent way in which the Council is spending the Erasmus Wilson bequest; £50,000 seems but a trifle for it to squander, unheeding and ill-advised. But the day of reckoning must come ere long, and the Members will then demand why, in the very face of a movement destined speedily to alter the constitution of a governing body, that body makes haste to dispose of property the trust of which is drawing near its term.

However, events are now crowding towards an issue, and almost ere your journal is in the hands of the profession the Privy Council will have received (on Nov. 11th) two deputations in opposition to the form of Supplemental Charter prayed for by the Council of the College, the one deputation coming from the Fellows of the College, the other from its Members; and we may add that we have the promise of the attendance and support of two or three prominent members of Parliament, who will, should the case pass on to a still higher Court of Appeal, watch vigilantly over our interests there. The matter has passed out of the hands of the College Council now. The laity has heard of our struggle, and no longer can the voice of the Members be stifled under the pillow of obstruction. We are, Sirs, your obedient servants,

WARWICK C. STEELE, } Hon. Secs. Assoc.
WM. ASHTON ELLIS, } M.R.C.S.

Grosvenor-road, S.W., Nov. 9th, 1887.

ON CARBOLIC ACID AS AN ANTIPYRETIC.

To the Editors of THE LANCET.

SIRS,—The important letter of Mr. Wiglesworth on the treatment of scarlet fever by carbolic acid has interested me extremely, and induces me to mention a few observations which I have lately made with the same drug, and the publication of which I have only hitherto deferred in hopes of adding to their number before taking that step.

The first case to which I shall refer, although a solitary one of its kind, appears to show that the acid is a decided and effective antipyretic. A healthy primipara was seized on the third day after delivery with rigors and pyrexia, which persisted for several days, in spite of the administration of quinine &c., and vaginal injections of solutions of carbolic acid and perchloride of mercury. On the eighth day, when the temperature in the axilla was 103·4°, I determined to apply strong carbolic glycerine (equal parts of the acid and glycerine) to the cervix uteri. A good many years ago some successful cases were described by Dr. Peter Eade, in THE LANCET, in which the cervix was smeared with this strong preparation, and I had already adopted this treatment in one previous case, which ultimately recovered. In that case, however, which occurred in the practice of a midwife, the symptoms were comparatively mild, and the application was not followed by any direct and marked effect on the temperature, and was repeated daily for a considerable time before the recovery of the patient was assured. I had little hope that an application so evanescent in its effects would be of much avail in the present case, and I determined to leave the acid in contact with the cervix for a considerable time, besides applying it to the fundus of the uterus. Accordingly, after passing an ordinary sound wrapped thickly round with cotton wool saturated with the medicament to the fundus, I left two pledgets of the same medicated cotton in the vagina and in close apposition to the cervix. These were passed through a speculum and had threads attached to them. Half an hour afterwards I was hastily summoned to see the patient, who was said to have become very weak. I found her in a state of partial collapse, with cold extremities. Pulse slow, but not weak; temperature in the axilla subnormal, —97·6° F. I instantly withdrew the plugs and administered a stimulant, and she soon rallied. It was quite clear that the carbolic acid had been absorbed in considerable quantity, and that it had exercised a decided antipyretic action; and, further, that, like other antipyretics, it had manifested a liability to produce symptoms of collapse. Next day I found the patient comparatively cool; temper-

Digitized by Google

rature 100·2°. I applied the medicament to the fundus and cervix as before, but did not leave any in contact with the latter. During the following two days she remained so well that I did not repeat the application, but on the third day the temperature had again risen to 103°. A cautious application to the cervix on this and the following day of only one minute's duration sufficed to check the pyrexia effectually and finally, and the patient made an excellent recovery.

Both Wood and Bartholow state that carbolic acid has been extensively used in diphtheria, scarlet fever, &c., but with disappointing results. It seems, however, to have been used only with a view to an antizymotic action, and probably in doses much too small to exercise an antipyretic influence. Both authors cite the results obtained by Emil Erls, who found that in mild putrid poisoning in animals the acid very much diminished the fever heat. After my experience of the above case, I felt a strong conviction that to produce an effective antipyretic action with the drug it was only necessary to administer it in sufficient doses. Two cases of typhoid shortly afterwards occurred in my practice, in children of one family, the first of which, however, I did not see till the case was well advanced. In the second case —a boy of fourteen years—the following notes were taken: On Aug. 3rd, several days from the commencement of the fever, the pulse was 120; respiration 28; temperature 104·6°. Ordered four grains of carbolic acid (in the form of carbolic glycerine, suitably diluted) every four hours, equal to twenty-four grains in twenty-four hours. On Aug. 5th, when the patient was next visited, and at nearly the same hour of the day as before, the temperature was 102·6°; pulse 110. On the 7th the temperature had fallen to 99 7°, and the pulse was 96. The patient had taken the acid regularly, and there was intense carboluria, the urine becoming so dark when rendered alkaline and exposed to the air that it required dilution with twice its volume of water before it became translucent in an inch test-tube. The drug was now discontinued for two days, and on the 9th the temperature had risen to 103·2°; pulse 108. He was again ordered three grains of the acid every four hours (eighteen grains in twenty-four hours), and on the 11th he felt much better, the temperature being 101·6°; pulse 94. He made a good recovery, and throughout the case he was remarkably comfortable, generally showing a tendency to somnolence after each dose of the acid, and presenting a marked contrast to his sister, who had gone through the fever before him.

Simultaneously with the above case I had under observation another boy of the same age, whose temperature, in spite of the administration of the same doses of the drug for several days, remained steadily at 103·2° and 103·4°. On examining the urine, however, there was not the slightest carboluria, and great was the surprise of patient and nurse (an indulgent sister) when I told them that the former had not taken a drop of the medicine, and that both had conspired to deceive me.

I have obtained beneficial results from the acid in other conditions attended with pyrexia, and can say that I have never seen a bad symptom from its use. In a severe case of erysipelas, with great pain and sleeplessness, it seemed to have both an anodyne and hypnotic influence, a good sleep being generally secured by a dose of five grains at bedtime. If seems to me that it would be of some importance from a scientific point of view to test more thoroughly than has yet been done the antipyretic action of carbolic acid before having recourse to the more complex substance, salol, whose efficiency in the same direction probably depends on the 38 per cent. of phenol which it contains.

I am, Sirs, yours truly.

Partick, Glasgow, Oct. 10th, 1887. ROBERT KIRK, M.D.

VENTILATION OF THE BEDS OF THE SICK.

To the Editors of THE LANCET.

SIRS,—In the Cambridge (Mass.) Hospital there is an arrangement for the ventilation of the beds not generally known; it is so effective that I wish to describe it. Beneath each bed is a ventilating tube of about eight inches diameter, fifty square inches area, leading directly through the floor to a foul air trunk, beneath which it communicates with the main ventilating chimney. About 2000 cubic feet of air an hour is thus drawn from beneath each bed. This ventilating tube is connected with the bed above by a four-inch pipe of tinned plate, with a proper cover and joints, which passes around the side or foot of the bed and into it beneath the clothing. This pipe is lengthened with one of the same size of pasteboard or other substance, a non-conductor of heat, reaching to any part of the bed. By this simple means foul air is removed as fast as formed, the bed kept free from odour, and the patient's body is no longer surrounded with contaminating gases. As the air presses inwards through the porous bed-clothing none escapes into the ward. Further, a two-inch flexible pipe is adjusted to that just described, and slipped over the hollow handle of the bed-pan when in use, carrying off odour from that also. In the same hospital similar means connect the beds in the private wards with the chimney of an ordinary fireplace, up which the pipe reaches about four feet to ensure a good draught with a moderate fire; the part in the chimney is of black iron. The advantages of such an arrangement in cases of sloughs, foul ulcers, cancers, and in fevers with frequent fæcal dejections, are obvious. It may be supposed that the passage of air through the bed would cool it too much. Practically it does not; probably the quantity of air passing is about the same as in beds ordinarily at the same temperature of the room, but in a different direction.—I am, Sirs, yours truly,

Cambridge, Massachusetts, U.S. MORRILL WYMAN, M.D.

VACCINATION.

To the Editors of THE LANCET.

SIRS,—The correspondence which appeared a few weeks since on the subject of vaccination induces me to send you a piece of evidence, which I have not seen recorded, but which, if borne out by the experience of others, forms a further proof that the protection afforded by vaccination varies in degree according to its character—namely, that a child vaccinated by one insertion can on the eighth day be further vaccinated from its single vesicle in three or more places; whereas if an attempt be made with a child having three vesicles at the same period to produce a fourth, it will not be successful. I have verified these experiments many times, under the first conditions with universal success, but always failing under the latter. One other fact worthy of mention is that, in cases in which fresh insertions are successfully made on the eighth day, the new vesicles mature a day or two earlier than in ordinary primary vaccinations, while the progress of the first vesicle towards scabbing is somewhat retarded.

I am, Sirs, yours truly,

Old-street, E.C., Nov. 7th, 1887. G. E. YARROW.

QUEEN'S COLLEGE, BIRMINGHAM.

To the Editors of THE LANCET.

SIRS,—My attention has this day been called to a paragraph in the letter of your Birmingham correspondent of Nov. 5th. From what he there says, it is obvious that the "halfpenny evening paper" to which he refers forms his sole reading, since the advertisement mentioned appeared according to general custom, in all the daily papers of this town, morning and evening, as also in the *British Medical Journal* and in your own advertiser. This misrepresentation coming from a special correspondent is quite inexcusable, and shows a very obvious animus against this College. I may add that the election of no candidate is "assured" until the council has confirmed it, as your correspondent ought, from past experience, very well to know. I trust that you will do me the favour of inserting this letter in your next issue, as the insinuations made against this College are both unfounded and unwarranted, and are likely to damage its reputation if not promptly contradicted.

I am, Sirs, yours faithfully,

BERTRAM C. A. WINDLE, M.A., M.D.,

Nov. 9th, 1887. Prof. of Anat. & Hon. Sec. Queen's Coll.

AN UNSUSPECTED DANGER.

To the Editors of THE LANCET.

SIRS,—A few days since, a lady, the head of a first-class school, showed me a large heap of filthy rags, cloth, and rubbish which had been taken from the inside of a number of bolsters and pillows, which had been unpicked for the purpose of the periodical cleaning and remaking which all

Digitized by Google

the school bedding undergoes—a laudable process, which is, unfortunately, not too common. The rubbish consisted of the most heterogeneous materials, and included portions of filthy coarse black serge, apparently parts of soldiers' old coat sleeves, pieces of dirty greasy silk dresses, old worsted braid from the borders of women's gowns, soiled linen rags, and coloured calico, even nuts and walnut shells and pieces of crinoline wire! The bedding in question was bought new a few years ago of an expensive and respectable upholsterer. The woman who was employed to do the unpicking works usually for the trade; she informed the lady that the practice of stuffing bedding &c. with dirty rubbish and rags was very general, and that few mattresses and bolsters contained only the material of which they were supposed to consist. May not this dirty and dishonest custom be—nay, is it not almost certainly—the cause of many of the mysterious and otherwise unaccountable outbreaks of infectious disease in schools and families? The practice is at once so filthy and so dangerous that it is high time public attention should be called to it, that it may be as far as possible guarded against, or, at any rate exposed.

I am Sirs, yours truly,

Folkestone, November, 1887. CHAS. E. FITZ-GERALD.

LIVERPOOL.

(*From our own Correspondent.*)

HOSPITAL SUNDAY AND SATURDAY.

THE annual meeting in connexion with the Hospital Sunday and Saturday collections took place on Monday, at the Town Hall, the Mayor, Sir James Poole, presiding. The committee, in their annual report, lamented a considerable decrease in the receipts compared with those of last year. The number of church and chapel collections was 312, realising £6029, against £6217 last year; the amount received in the Hospital Saturday boxes reached £2851, against £3135 last year. The amount distributed by the committee this year was £8750 in addition to £185 voted last year to the Hospital for Women, but held in abeyance; this was forwarded to the treasurer of that institution. What is much needed is greater effort on the part of the working men. By systematic and regular contributions of a halfpenny per week an enormous addition might be realised. Owing to peculiar circumstances Liverpool has felt the depression of trade probably more than any other city; this is the explanation of this decrease.

THE HOSPITAL FOR WOMEN.

The following considerable additions and improvements have lately been made in this hospital. A large operating theatre has been provided, two new wards have been opened, and a day room for patients has been furnished through the kindness of two members of the Ladies' Committee, whilst additional dormitories and a day room for nurses have materially increased the comfort of the hospital.

INTERESTING ABDOMINAL SECTION.

The following very interesting case recently occurred in the practice of Dr. Macdonald of Walton. The patient, believing herself to be six months pregnant, sent for Dr. Macdonald on account of abdominal pain and tenderness, with general prostration. Dr. Grimsdale was consulted. Both he and Dr. Macdonald, believing the source of the almost fatal hæmorrhage to be the ruptured sac of an ex-fœtation, advised operation as the only apparent chance of the patient's survival. Dr. Briggs, surgeon to the Hospital for Women and to the Lying-in Hospital, assisted by Drs. Macdonald and T. B. Grimsdale, opened the abdomen and released from among the intestines and behind the omentum a large quantity of fluid and clotted blood, which had been poured out from the upper portion of the ruptured sac. The sac contained a six months fœtus, which was removed, and both the peritoneal cavity and the sac were drained by glass tubes. The pregnancy, tubal in the first instance, had expanded the left broad ligament, and finally ruptured, at the unusually late period of the sixth month. The progress so far, up to the twenty-seventh day after operation, has been satisfactory.

THE NORTHERN HOSPITAL.

Monday was an unusually busy day at the Northern Hospital, there being, in addition to the ordinary patients, a large number of accidents, several of a very severe nature. Of the latter, one was that of a baker, who by a fall had sustained a concussion of the brain and fractured arm; a labourer falling from the roof of a house sustained a fractured thigh; and a man, seventy-one years of age, sustained a serious wound of the head, by falling from the quay into a boat. These were all taken to the hospital in an ambulance.

Liverpool, Nov. 8th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE COLLEGE OF MEDICINE.

THE foundation stone of the University of Durham College of Medicine was laid here on Nov. 3rd by his Grace the Duke of Northumberland, Lord-Lieutenant of the county, with the usual ceremonies. A description of the building has already appeared in THE LANCET. The luncheon, which took place afterwards in the Assembly Rooms in this city, was certainly the most important medical gathering I have ever seen in the north, and was at once a brilliant and representative meeting. Great praise is due to the committee and secretaries for the excellent arrangements made to provide for about 300 guests. The historical statement read by Mr. H. E. Armstrong on the occasion was of much interest, but must be condensed here. The first medical school in Newcastle was begun in 1832-3. The credit of this beginning is entirely due to Mr. (afterwards Sir) John Fife. After a removal to larger premises in 1834, it was recognised by the University of London and the Royal College of Surgeons of England. This school was fully equipped, and had a fairly prosperous career until it was pulled down to make way for some railway extension; so that again the school had to shift its quarters, and after some changes in its constitution it was in 1852 united to the University of Durham, and the premises known as Neville Hall became its abode. From this time the work of the College has increased greatly, as the figures show that the school of Sir John Fife's foundation has from a commencement of ten students or so recently come up to an average of two hundred. Again the demands of the railway company have turned the College out, and compelled them to erect this new building. It was mentioned that the tenure of office of the present President, Dr. Heath, as well as two members of the staff, Drs. Gibson and Gibbs, had extended over an uninterrupted period of forty years. In preparing the statement, the thanks of the College were given to Dr. Embleton, whose aid was most valuable, who had filled the position of lecturer from 1839 to 1872, and who during many years ably filled the offices of Reader in Medicine of the University and Registrar of the College. The Duke of Northumberland, the Dean of Durham, and the Mayor and Sheriff of Newcastle spoke at the luncheon, but the address of the President (Dr. Heath) was the speech of the occasion; broad, suggestive, and always eloquent, he set forth with much acumen the utility of a College of Medicine in a large community, and showed the value to the public health of proper investigations in animal pathology, and their value to the agriculturalist, and believed that the purely scientific chairs in the new College should be endowed. He pointed out in a most practical manner that what they were now doing would cost £25,000, but to complete the College to its full extent, with residential halls, would require another £25,000, or £50,000 in all. He said the College of Medicine had never hitherto asked any help from the public or from Government. It had been completely self-supporting, and now he was quite sure that his colleagues were prepared to raise upon their own responsibility a considerable sum; but he hoped that in this important matter they should not be left without some measure of support from the public. They had already had some encouragement from some of their members. They had received from Dr. Gibbs of this city the munificent donation of £1000, and he thought it only fair to say that

Digitized by Google

as Dr. Gibbs was no longer a lecturer, it made the gift the more generous, as he received no emolument from the College.
Newcastle-on-Tyne, Nov. 8th.

EDINBURGH.

(From our own Correspondent.)

THE UNIVERSITY LORD RECTORSHIP.

LAST week the Marquis of Lothian, K.T., who holds the office of Secretary for Scotland under the present Government, was elected without opposition to the post of Lord Rector of the University, in the room of the late Lord Iddesleigh. The duties of his three years' tenure of office are to preside at meetings of the University Court, to appoint an assessor to a seat at the same body, and to address the undergraduates, his constituents, at least once during the time he acts as their representative. An uncontested election for the office has been a very rare occurrence, and is in striking contrast to the active party warfare now in progress in Aberdeen University, where Mr. Goschen and Mr. John Morley are candidates for the vacant Rectorship, and in Glasgow, where the rival claims of Lord Rosebery, Lord Lytton, and Professor Max Müller are actively canvassed among the electors. Lord Lothian's unanimous election is no doubt largely due to his position as chief minister for Scotland, and to the fact that, during his tenure of the Scottish Secretaryship, he has won golden opinions from all classes of the community by the energy and ability with which he has discharged the duties of his office. As the probable author of the next Universities Bill, great things also are expected of him, and there is no doubt that his well-known moderation will give him a chance of succeeding to general satisfaction where others would inevitably fail.

PARTIAL AMPUTATIONS OF THE FOOT.

A largely attended meeting of the Medico-Chirurgical Society was held on Nov. 2nd., at which an important surgical paper was read by Mr. C. W. Cathcart, discussing the question, "Should Partial Foot Amputations be Abandoned?" As a text for his paper Mr. Cathcart exhibited two cases of partial amputation of the foot, a Chopart and a Lisfranc, along with one of amputation at the ankle joint (Syme), and commented on the marked superiority of the first two over the last in that greatest desideratum, facility of progression. As stated by Mr. Cathcart in his paper, the question seems to be narrowed to one of mechanical expediency between different schools of artificial limb makers. Mr. Cathcart has put the leading firms in the witness box by addressing them a series of questions on the subject; and as their evidence is far from unanimous, he has proceeded to investigate the whole matter *ab initio*, and has come to a conclusion wholly in favour of the partial amputations. Beginning with an account of the physiology of progression, based on the researches of the Webers and those recently published by Marey, Mr. Cathcart drew attention to the enormous value in progression of the ankle joint proper as retained in Chopart's amputation, and of the inter-tarsal joints as preserved by Lisfranc's operation—advantages to a patient of so practical a value in ensuring his stability as to outweigh completely the greater neatness claimed for the artificial foot fitted after Syme's amputation. Mr. Cathcart reiterated the dictum of the older surgeons, that where operation is performed for trauma, that method which saves the greatest extent of tissue consistent with the vitality of the stump is in every case to be emphatically preferred. After a short discussion, in which Mr. A. G. Miller and Professor John Chiene both homologated the opinions stated in his paper, Mr. Cathcart replied with a brief acknowledgment of the careful attention with which he had been heard.

THE PRESIDENT'S VALEDICTORY ADDRESS.

Professor T. Grainger Stewart then delivered his valedictory address to the Society at the close of his two years' tenure of the presidential chair. He reviewed the work done by the Society during the last two years, and took a general survey of the present position of the profession in Edinburgh. In speaking of the Medico-Chirurgical Society itself, the retiring President took occasion to note the many recent gaps in its foremost ranks occasioned by the visitations of death. In a few sympathetic sentences he spoke of the deeply lamented loss of such men as the late Dr. Angus Macdonald, Dr. Rutherford Haldane, Mr. William Brown, Dr. John Bishop, Dr. Dunsmure, Dr. Sidey, and Dr. Cumming, paying a generous tribute to the professional eminence, the geniality, and the public services of each, no less than to the loyalty with which each had striven in his own sphere to hold high the standard of professional integrity, and to assure it its high prerogative as a noble calling. In turning to review the present position of the profession in Edinburgh, Professor Stewart dealt with four aspects of the subject, each of cardinal importance. As guardians of the public health, as advisers of the general public in their most personal and private affairs, as investigators of the causes and preventives of disease, and as teachers of a rising generation of medical men—in all these relations he inquired into the present condition of the school, and though he found much ground for congratulation in the inquiry, yet on the many points where he encountered the opposite, he did not hesitate to unmask the evil and suggest measures for its reform. Professor Stewart is succeeded in the presidency of the Society by Dr. John Smith, Vice-President of the Royal College of Surgeons, and Surgeon-Dentist for Scotland to Her Majesty the Queen.

DUBLIN.

(From our own Correspondent.)

IRISH PRISONS BOARD.

DURING the year ending March last eighty-five inmates of local prisons were certified to be insane, of whom only six were considered sane on admission to the various local prisons. The medical adviser of the Board has already drawn attention to the unfavourable influence on the lunatics of their committal to prison instead of direct to the asylum. In seventy-nine out of the eighty-five of the cases admitted to local prisons during the year no reasonable doubt could be entertained respecting the insanity of the prisoners committed. The medical officers of the local prisons with justice frequently record their surprise that cases of manifest insanity should be sent to prison. The water supply of Maryborough Prison has occupied much attention during the past year. This prison stands on a somewhat lower level than that occupied by the County Infirmary, and is separated from it by a public road, while the existing arrangements in the infirmary for the disposal of excreta are not of a satisfactory character. On one occasion during the past year enteric fever occurred in Maryborough Prison and the Board's medical adviser entertained no doubt that it arose from pollution of the wells by percolation through the gravelly subsoil of water from a watercourse passing from the infirmary in the vicinity of the prison. The deaths in local prisons for the year amounted to nine, six of which were due to pneumonia. Seventy-seven prisoners were released on medical grounds, but some of the alleged causes seem trivial enough—viz., abscess of ear, hernia, enlarged cervical glands, piles, bone in throat, &c.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At a meeting of the Council held on the 3rd inst., Dr. C. H. Robinson was elected an Examiner in Physiology, to examine candidates for the Conjoint Examinations held by the College and the Apothecaries' Hall of Ireland. Dr. Hayes has been elected by the Apothecaries' Hall an Examiner in the Practice of Medicine for the Conjoint Scheme between it and the College of Surgeons.

BRITISH MEDICAL ASSOCIATION: DUBLIN MEETING.

The subscriptions to the Reception Fund of the Dublin meeting of the British Medical Association held last August, amounted to £1501 10*s.*, and the expenditure to £1442 11*s.*, leaving a balance in hand of £58 19*s.* A meeting of the subscribers will be held on Wednesday, the 9th inst., to determine how this surplus shall be disposed of.

DUBLIN HOSPITAL SUNDAY FUND.

The annual collections in aid of this Fund will take place on Sunday next, the 13th inst. Last year a sum of £4158 0*s.* 3*d.*

Digitized by Google

was collected, being a decrease of £310 5s. 5d. as compared with the year preceding. Since the establishment of the Fund in 1877 no less than £53,089 8s. 10d. has been obtained, and £49,334 2s. 6d. distributed among the various hospitals participating in it.

MEATH HOSPITAL, DUBLIN.

The introductory lecture at the opening of the winter session was delivered by Dr. A. Foot on Monday. On the same evening a dinner for the reunion of old students and governors took place at the Shelbourne Hotel, presided over by Sir George B. Owens, M.D.

ROYAL HOSPITAL, DUBLIN.

It is rumoured that this institution will shortly be closed, and a new barracks erected on the North Circular Road near the Phœnix Park.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

The opening meeting of the Pathological Section of the Academy was held on the 4th inst., when Dr. Ball, the President, gave an inaugural address, in which he referred to the necessity of pathological research, and of establishing a pathological institute. Dr. Finny exhibited an hour-glass contraction of the stomach, and Dr. E. H. Bennett detailed a very interesting case of phlegmasia alba dolens, and exhibited the parts affected.

DEATH OF DR. J. VALENTINE BROWNE OF GALWAY.

An eminent surgeon, one well known in the west of Ireland (Dr. J. Valentine Browne), died last week at his residence, Prospect Hill, Galway. The deceased filled the chair of Surgery in the Queen's College, Galway, and was surgeon to the County Galway Infirmary. He was also an Examiner in Surgery in the Royal University of Ireland. He was greatly esteemed, and the utmost sympathy is felt for his family in their sad bereavement.

Mr. Henry Quinn has left £200,000 to be expended in charitable purposes in Newry.

Dublin, Nov. 8th.

BELFAST.

(From our own Correspondent.)

THE BELFAST DISTRICT LUNATIC ASYLUM.

WE understand that at their next monthly meeting a very important matter will have to be decided by the governors of this asylum. The population of the districts to which the Belfast Asylum belongs—co. Antrim, Carrickfergus, and the borough of Belfast—is about 450,000, and it is calculated that some 800 or 900 patients must be provided for in the Belfast District Lunatic Asylum. The present accommodation is, in this building, for 550. As in other parts of the kingdom, insanity has been found here to increase concurrently with the increase of the population. The question before the Board has been how to secure the additional accommodation. There are now 560 patients in the house, in addition to eighty others at Ballymena Workhouse, a sort of off-shoot of the Belfast Asylum for harmless patients. It is apparent, then, that the existing accommodation, which is for 550 patients only, at the Belfast Asylum is overtaxed, and this in the future will not be diminished. Three plans have been suggested to get out of the difficulty. It has been proposed to enlarge the asylum within its present grounds; but Dr. Nugent, Lunacy Inspector in Ireland, has reported that it would be "inexpedient to make any further additions to the Belfast Asylum, inasmuch as the number of inmates to the extent of the grounds—viz., ventilation, exercise, and occupation—would be disproportioned, and these factors, together with day-room accommodation, form an important feature in the care and treatment of the insane." Again, it has been suggested to build a new asylum to accommodate 300 patients; but to erect and furnish thoroughly such a structure would cost £30,000. A third plan is to utilise a workhouse, which might be done for £4000 or £5000. A decision will have to be made on these questions by the governors next month.

THE ROYAL UNIVERSITY.

We understand that the Royal University has recognised the Belfast Ophthalmic Hospital and the Ulster Eye, Ear, and Throat Hospital as institutions from which certificates of attendance by students will be received.

THE BRITISH DENTAL ASSOCIATION.

A meeting of the Belfast dentists was held in the Royal Hotel on Friday, under the auspices of the Irish Branch of the British Dental Association. We learn that the annual meeting of the Association is to be held in Dublin towards the end of August, 1888. The honorary secretary of the Irish Branch, Mr. Pearsall, was present at the meeting, and explained the objects and aims of the Association, and advised all who were not already members to join the Association. We understand that all present promised to do their utmost to make the meeting a success, and those who were not already members promised to join the Association.

Belfast, Nov. 8th.

EGYPT.

(From our own Correspondent.)

SANITARY DEPARTMENT.

THE work of sanitation is slowly progressing in spite of much passive resistance and an empty exchequer. During the past summer a monthly periodical called *El Salia* (Hygiene) has been started by the Government as a useful means of spreading sanitary knowledge among the native doctors. It consists of thirty-two pages of closely written Arabic character, and at present 500 copies are sold every month at 1s. each. It contains translations of papers from English and French journals and original articles by a committee of supporters. This publication does not in any way interfere with its native colleague, *The Cure*, which treats of matters purely medical and surgical. Five dispensaries have lately been established in provincial towns, and eight others will shortly be opened. These supply a long-felt want, and gratuitously give medicines to the poor, while the Government charges small sums to rich patients. There are now nine Englishmen in the sanitary service, all hard-working sanitary officials. It is three years and a half since the first Englishman was appointed to this department.

HEALTH OF THE BRITISH TROOPS.

The strength of the troops in Cairo and its desert suburb of Abbasiyeh is to-day 3600, with a sick-rate from all causes of 380, or 10·5 per cent. The sick are made up of 144 simple continued fever cases, 45 enteric, 13 scarlatina, and 178 venereal and other diseases. The scarlatina cases are all very mild, and include one officer, and are only of interest because the disease is very rare in Egypt. There is no evidence to show that these cases can have had the disease transmitted to them from England by letters or other articles by post. The enteric patients, like those always to be seen in this country, occur among young soldiers less than twenty-four years of age. The simple continued cases are greatly in excess of the ordinary rate, and account for the general high percentage. They come chiefly from the Welsh Regiment, which has had a sick-rate during October varying from 10·3 to 16·5 per cent. This is partly due to the regiment having previously suffered from malaria at Mauritius and the Cape of Good Hope, and partly because the Kasrel Nil barracks have been inundated by the exceptionally high Nile. The regiment has now been placed under canvas in the desert, and it is confidently expected that the fever will at once disappear. The Royal Engineers, occupying the same barracks, have had a sick-rate during October of from 5·3 to 10·1 per cent. The Cheshire and 7th Fusilier Regiments, which are in the Citadel barracks, presumably removed from all damp and malaria, have yet had sick-rates varying from 6 to 11 and from 5 to 10 per cent. The 20th Hussars, who occupy barracks at Abbasiyeh, surrounded by the healthiest desert air, have had an October sick-rate of 2·5 to 5 per cent. only. But it may be mentioned here that the Egyptian army, numbering 1500 natives, all quartered at Abbasiyeh, had only six cases of simple continued fever admitted to hospital during September, while in October the number has been raised to thirty-eight. The Cheshire Regiment is under orders for Rangoon, and will be relieved by the Rifle Brigade, who are at once to be quartered in camp on the Mokattam heights above the Citadel. In Alexandria the strength of the detu-

Digitized by Google

pying force is now 1028, with a sick-rate of 91, or 8·8 per cent. The Yorkshire Regiment there has had during October a rate between 8·3 and 11 per cent. There are now only two cases of enteric and fourteen of simple continued fever; nearly all the remainder are made up of venereal disease and prickly heat.

THE NILE INUNDATION.

Last year there was a very fairly high Nile, as judged by its maximum at Cairo, but this year it rose four feet higher, and remained at this alarming level for a whole month, beginning on Sept. 21st. It has now subsided eight feet, and is continuing to fall at the rate of more than two inches a day. The last very high Nile was in 1878, when it rose even two feet higher than this year, but on that occasion it broke its banks in several places, and only remained at its maximum for two days.

SIMPLE CONTINUED FEVER IN CAIRO.

The civilian population, both European and native, has been suffering since the middle of September from a fever, lasting from three to six days, commencing with pains in the head, back, and muscles, but not in the joints. The temperature seldom rises higher than 102°, but is occasionally seen for one night at 103°, and in very rare cases 104°. The tongue is coated white, and the bowels are undisturbed. Patients complain of nothing but lassitude, so long as they lie still, but suffer from muscular fatigue and neuralgia if they continue to work. The malaise is ushered in sometimes by vomiting, but not by rigors. The liver and spleen are not enlarged, and it is doubtful whether quinine can shorten the attack. Antipyrin relieves the feverishness and other symptoms. There is no eruption, but a few of the white patients have an erythematous flush, chiefly on the face and chest, but to be seen also on the trunk and limbs, never lasting more than two days. There have been no deaths, no relapses, no remissions, and no hæmorrhages. The weakness left by the fever is much greater than would be expected from so mild an attack. Most observers agree that there is no evidence in favour of contagion, but one Greek doctor maintains that he has seen cases of wives contracting it from husbands, and children at the breast taking the disease from their mothers. On the other hand, there are many cases of one partner of the conjugal bed not taking it from the other. The fever is undoubtedly due to excessive Nile infiltration, aided probably by the insanitary subsoil of the town's cesspools. There are no grounds for believing that this fever is analogous to dengue as known in India and America, though dengue occurred as an epidemic in Cairo in 1880, and is said to have been sporadic on the Suez Canal ever since. The fever is already abating, and does not attack recent arrivals in the country, though it has not spared those Europeans who spent the whole summer in Egypt.

Cairo, Nov. 1st.

THE SERVICES.

MR. FITCH, Surgeon on H.M.S. *Sphinx*, on the East Indian Station, has been invalided, and sent to England suffering from intermittent fever contracted recently at Kurrachee.

WAR OFFICE. — Grenadier Guards: Brigade Surgeon Arthur G. Elkington has been placed upon retired pay, with the honorary rank of Deputy Surgeon-General (dated Nov. 5th, 1887); Surgeon-Major W. R. Lane, Scots Guards, succeeds to the appointment of Principal Medical Officer of the Brigade of Guards by the retirement of Brigade Surgeon Elkington, but will retain it only until September next, as he himself will then have to retire for age.

ARMY MEDICAL STAFF.—Surgeon-Major Espine Charles Robert Ward, half-pay, has been granted retired pay (dated Oct. 28th, 1887); and Quartermaster and Honorary Captain William Amphlett Moss is granted retired pay, with the honorary rank of Major (dated Nov. 5th, 1887).

ADMIRALTY.—The following promotion has been made:—Staff Surgeon Frederick McClement, M.D., to be Fleet Surgeon in Her Majesty's Fleet (dated Oct. 25th, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Northumberland Fusiliers:—Duncan Stewart, Gent., to be Acting Surgeon (dated Nov. 5th, 1887).

VOLUNTEER MEDICAL STAFF CORPS.—The London Division: Surgeon Adam Watson is granted the honorary rank of Surgeon-Major (dated Nov. 5th, 1887).

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the College, held on Thursday, Nov. 10th, the Minutes of the last meeting were read and confirmed.

Two Members were removed from being Members of the College, and called upon to return their diplomas, as required by Clause 5, Section xvi., of the Bye-laws.

The appointment of Pathological Curator was deferred.

The President reported the result of the meeting of the Fellows and Members, and read the resolutions carried at the meeting (*vide* our report of the proceedings, p. 967). After the reading of the first resolution, it was proposed by Mr. Sydney Jones and seconded by Mr. O. Pemberton, "that Members of the College of a certain standing should be empowered to take part in the election of members of the Council." After discussion, Mr. Durham moved and Mr. Lawson seconded: "The previous question—that this motion be not put, and that the Council do proceed to the next business."

After the reading of the second resolution the following motion was passed:—"That the Council accede to the request contained in resolution No. 2, carried at the meeting of Fellows and Members of the College on the 3rd inst.; and in forwarding resolution No. 1, passed at the meeting, the Council desire to state that they have repeatedly and fully considered the several points mentioned in the foregoing resolution, but do not propose to ask for any change in the terms of the Charter for which they have applied to the Privy Council."

A letter was read from Mr. C. Heath resigning his appointment as member of the Court of Examiners. The resignation was accepted, and the vacancy is to be filled up at the ordinary meeting in December.

A letter was read from Mr. Wilde, reporting the transfer into the name of the College of the several stocks forming the residue of the estate of the late Sir Erasmus Wilson.

The consideration of Mr. Hutchison's motion of Aug. 4th was postponed.

Obituary.

W. F. TEEVAN, F.R.C.S., B.A. LOND.

IT is with deep regret that we chronicle the death of Mr. William Teevan at Hawkhurst, on Oct. 22nd, at the age of fifty-three. Forced suddenly—in the very prime of life and vigour of work, with fame and fortune already within his grasp—to withdraw from the ranks of his profession, he lingered for six years, awaiting the termination of a career which was as melancholy in its completion as it was brilliant in its commencement and course. Educated at University College, London, he held, after taking the Fellowship of the College of Surgeons and the B.A. Lond., the House Surgeoncy and the Assistant Demonstratorship of Anatomy to the Hospital. Joining the West London Hospital, he applied himself zealously to clinical and operative surgery. His first important publication was stamped with that thoroughness which was the characteristic mark of his after-work. It was an experimental inquiry into the causation of fractures of the skull, and his conclusions were based upon the effects of shot wounds of the skull-cap. This he published in a *brochure* entitled "The Causation, Diagnosis, and Treatment of Fractures of the Internal Tables of the Skull." Other works of an original character followed, but his appointment to St. Peter's Hospital for Urinary Disease in 1866 lent a new direction to his energy. His contributions gained for him a deservedly high opinion in the estimation of the profession, both at home and abroad, and his name and opinions are often quoted by our continental and American *confrères*. The most important are "Lithotomy," "The Dia-

Digitized by Google

gnosis and Treatment of Stricture of the Urethra," "The Treatment of Stricture, Enlarged Prostate, and Stone" (Lettsomian Lectures, 1880), and "Incontinence after Lithotomy in Children."

Whilst suffering from, and with the certain knowledge of, an incurable disease, he took an able and active part in the Medical Congress of 1881, but in 1882 aortic mischief compelled him to relinquish his practice, and he retired to Folkestone. In 1883 the terrible trial of loss of sight was superadded to his sufferings, and just before the end his reason became affected.

Mr. Teevan was ever alert to receive and to test innovations, ever ready to strike out fresh lines of practice himself, and unbiassedly to publish his results. A man is known by his surroundings, and we have often estimated the care, thought, and thoroughness of Mr. Teevan's work by examining his well-filled shelves of well-thumbed books. We have often appreciated the notes, memoirs, and apposite comments which mark Mr. Teevan's collection of the literature of urinary surgery of this century. His museum of instruments was of extreme interest. It was his hobby. It contained his failures and his successes in invention. His out-patient department had many visitors. His explanations of difficult cases were sound, terse, and lucid. His kindness to his patients was proverbial; his generosity great. Many are the tales of monetary help and kindly sympathy which have reached the ears of his co-workers. A brilliant operator, a loyal colleague, a genial friend, Mr. Teevan has passed away prematurely, leaving behind him a personality to imitate and regret.

ROBERT GREENHALGH, M.D.

DR. ROBERT GREENHALGH, whose death took place somewhat suddenly at his residence in Cavendish-square on the 7th inst., received his professional education at the Middlesex Hospital, and afterwards studied at Munich and Vienna. In 1842 he became a member of the Royal College of Surgeons of England, and in 1859 a member of the Royal College of Physicians of London, having previously, in 1853, taken the degree of M.D. at the University of St. Andrews. Some time ago Dr. Greenhalgh was compelled, through bronchial asthma and other physical ills, to retire from practice, though he saw a few old patients even within a few weeks of his decease. For many years he held the offices of Obstetric Physician and Lecturer on Midwifery at St. Bartholomew's Hospital, and also numerous honorary posts, amongst others that of Consulting Physician to the Samaritan Hospital for Women and Children. In 1844 Dr. Greenhalgh was President of the Medical Society of London.

We have received from a correspondent the following particulars of his last illness: "Dr. Greenhalgh had been at home after a recent sojourn at Tunbridge Wells for about fourteen days. During this time he had been well enough to come downstairs, and had not suffered more than was usual with him at this time of the year from his bronchial asthma. On Monday, Nov. 7th, however, his breathing became very difficult, and during the afternoon he seemed much exhausted. At 7 o'clock his dinner was taken to him in his own room, and he was able to eat some of it. He then lay down, thinking to get some sleep, and so he passed away. His daughter, who was with him, sent for Dr. Ferrier, who lived next door, and he came immediately, to find Dr. Greenhalgh dead, soon after 8 o'clock on the Monday evening."

THE LATE DR. WILSON FOX.—Mr. Francis George Heath, editor of *Illustrations*, having forwarded to Her Majesty a copy of the November issue of that magazine, containing a portrait (never before published) of the late Dr. Wilson Fox, has just received the following message from Sir Henry Ponsonby:—"I am commanded by the Queen to thank you for the copy of *Illustrations* containing the memoir and excellent portrait of Dr. Wilson Fox."

MEDICAL MAGISTRATES FOR MIDDLESEX.—William Adams, F.R.C.P., Tower Lodge, Regent's-park-road, and Maurice Davis, M.D., Brunswick-square, have been placed upon the Commission of the Peace for the County of Middlesex and the City and Liberty of Westminster.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations for the diploma of Member, were, at a meeting of the Council on the 10th inst., admitted members of the College:

*Abram, J. Hill, L.R.C.P.Lond., Carter-street, Liverpool.
*Anderson, G. Reinhardt, L.R.C.P.Lond., Westborne-villas, West Brighton.
Adams, Gerald Wheatly, L.R.C.P.Lond., Greek-st., Stockport.
Arnim, H. C. Leffler, L.R.C.P.Lond., Hinde-street.
Atkinson, Guy C. Barlow, L.S.A., Danby Parsonage, Grosmont.
Baxendell, Arthur, L.S.A., Rose Hill, Denton, Manchester.
*Bearblock, W. J., L.R.C.P. Lond., Stoke-terrace, Devonport.
Blackie, A. Babington, L.R.C.P.Lond., Bierska-road, Clapham.
*Booth, Daniel, L.R.C.P.Lond., Wall-street, Ripley, Derbyshire.
Braine, Charles Carter, L.R.C.P.Lond., Maddox-street.
*Browning, Edgar, L.R.C.P.Lond., Clarendon-sq., Leamington.
Bullock, T. Warren, L.S.A., Spring-grove, Isleworth.
*Buswell, Ferberd R., L.R.C.P.Lond., Ladbroke-grove-road.
*Campbell, H. J., L.R.C.P.Lond., Brackley, Bexley-rd., Erith.
Capes, Robert, L.R.C.P.Lond., Canbury House, Kingston.
Carnall, Edward, L.S.A., Fowey, Cornwall.
Castel, A. Leo, L.R.C.P.Lond., Osnaburgh-st., Regent's-park.
Challenor, W., L.S.A., Bismark-road, Highgate.
Cheatle, G. Lenthel, L.S.A., Vereker-road, West Kensington.
*Cole, Samuel J., L.R.C.P.Lond., Bery, Haitland, North Devon.
*Comerford, Beaumont Harry, L.R.C.P.Lond., St. George's-road.
Cotes, Digby Francis Baynes, L.S.A., Penton, Swindon, Wilts.
Daniel, E. Clement Sephton, M.B.Edin., Brampton, Hunts.
Davis, William, L.R.C.P.Lond., Manor-road, Brockley.
Dixon, C. Henry, L.R.C.P.Lond., Abingdon, Berks.
Dodd, P.Vernon, L.R.C.P.Lond., Petherton-rd., Highbury-new-pk.
Evans, W. Norman, L.R.C.P.Lond., Thurloe-road, Hampstead.
*Fawsett, Frank, L.R.C.P.Lond., Fairlight, Hampton Wick.
Finnicane, Morgan Ignatius, L.S.A., Wilton House, Southsea.
*Fisher, W., L.R.C.P.Lond., Erfurt Lodge, Greenwich.
*Gibbens, Frank Edward, L.R.C.P.Lond., Hunter-street.
Gilchrist, T. Casper, L.S.A., Victoria-street, Crewe, Cheshire.
Gilford, Hastings, L.R.C.P.Lond., Beech-grove, Redhill,
*Gimson, W. Douglas, L.R.C.P. Lond., Witham, Essex.
Goodchild, Nathaniel J., L.R.C.P.Lond., Sidney House, Highgate.
Griffiths, W. A., L.R.C.P.Lond., Redgrave-villas, Victoria-road.
*Hammersley, P. H. Vickers, L.R.C.P.Lond., Bridge House, Leeks, Staffs.
Hemming, Claude Philip, L.S.A., Highfield, Bishop Waltham.
Hemming, John J., L.S.A., Concrete House, Swindon.
Hillyer, W. H., L.R.C.P.Lond., Ellerslie, Balham-park-road.
Hinde, F. R. Berthon, M.B., C.M.Ed., General Hosp., Nottingham.
*Hogarth, Christopher Whewall, L.R.C.P.Lond., St. Lawrence-rd.
*James, C. Henry, L.R.C.P.Lond., St. Thomas's Hospital.
*James, Coram Llewellyn Stuart, L.R.C.P.Lond., Windsor-road, Forest-gate.

The following gentlemen having passed the necessary examinations were at a meeting of the Council on the 10th inst. admitted Licentiates in Dental Surgery:—

Ackland, Robert, Southernhay, Exeter.
Badcock, John Henry, Tottenham-court-road.
Colyer, J. Frank, Hazeldene, Thurlow-park-road, West Dulwich.
Goard, Thomas Arthur, Portland-square, Plymouth.
Jones, Albert Sidney, Bridge House, Stamford.
Kendall, William Henry, Chapel-street, Warwick.
Miller, Frederick Tayler, Baron's-court-road, West Kensington.
Morley, Charles Reginald, London-road, Derby.
Picton, Henry, Annandale, Rossiter-road, Balham.
Saul, Barnett Bendet, Hereson, Ramsgate.
Smith, Arthur Hopewell, Lindon House, Boston, Lincolnshire.
Stoner, Harry John, Western-road, Brighton.
Wakefield, Stanley Bennett, Bevan-villas, Lower Richmond-road, Putney.

VICTORIA UNIVERSITY, MANCHESTER.—On the 4th inst. the degree of Bachelor of Medicine was conferred on the following gentlemen:—

Bury, Frederic Charles, Owens College.
Robinson, Frederick Gardner, Owens College.

NEW COTTAGE HOSPITAL.—Mr. J. W. Maclure, M.P., has decided to erect and equip a cottage hospital for Hulme.

LITERARY INTELLIGENCE.—A new work, entitled "Tätowiren: Narbenzeichnen und Körperbemalen," by W. Joest, is about to be issued in Berlin by Archer and Co.

VACCINATION GRANT.—Mr. Ernest S. Medcalf, public vaccinator, Steyning Union, Hove, has received the Government grant for successful vaccination.

HEREDITY AND NURTURE.—The proposed course of lectures by Mr. Francis Galton on this subject at the South Kensington Museum is unavoidably postponed.

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.—The Earl of Meath has consented to take the chair at the ninth festival dinner of this charity, to be held at Willis's Rooms on Thursday, the 24th inst.

MEASLES.—An epidemic of measles prevails in several of the villages and hamlets of East Kent. At Boughton a large portion of the juvenile population are attacked.

THE DENTAL HOSPITAL OF LONDON.—The Annual Dinner of the staff and past and present students will be held on Saturday, December 3rd, at the Holborn Restaurant, under the presidency of George Gregson, Esq.

TWO deaths from hydrophobia have just occurred at Bradford. During the past two years the police authorities of that town have, under the dog regulations, destroyed more than 2000 animals.

A FRENCH photographer has shown that the light emitted by the glowworm is possessed of actinic properties sufficient to produce a distinct photographic image of the holes in a cardboard box in which one of these animals was crawling about.

ROYAL SOCIETY.—Amongst the names recommended by the President and Council of the Royal Society for election into the Council for 1888, at the anniversary meeting on the 30th inst. are those of Sir W. Bowman, Prof. D. Ferrier, and Dr. A. Gamgee.

FORMING part of the Lord Mayor's Procession on Wednesday was a company of the Volunteer Medical Staff Corps, which, like other portions of the pageant, would have appeared to better advantage had the weather been more favourable.

SANITARY REFORM IN TURKEY.—A reduction of the sanitary dues on shipping, with certain quarantine reforms, having been decided upon in Constantinople, an international committee has been appointed to draw up the new tariff and rules.

MEDICAL SCHOLARSHIPS.—The Entrance Scholarship, of £125 at St. George's Hospital Medical School, open to the sons of medical men, has been awarded to Mr. R. G. Turner. At the University College, Liverpool, the Holt Tutorial Scholarships, value £100 each, have been awarded to Mr. W. Thelwell Thomas and Mr. Randall Leigh.

THE prospectus of the forthcoming International Exhibition to be held at Brussels has been issued. The exhibits are divided into forty-nine classes, amongst which are the following:—Scientific Instruments, Medicine and Surgery, Chemistry and Allied Industries, Pharmacy, and Foods.

THE Association of Public Sanitary Inspectors entered upon the fifth year of their proceedings on the 5th inst., when a large body of members attended at the Westminster Town Hall to hear the inaugural address of Mr. Hugh Alexander, the chairman of the Council for the ensuing year.

CENTENARIANS.—On the 5th inst., Mrs. Michael of North Somercotes, Lincolnshire, attained her hundredth year, and on the same day was recorded the death of Mrs. Margaret Brace at the age of 104 years.—On the 6th inst., Mrs. Rees, living near Llandovery, celebrated her hundredth birthday.

LEAMINGTON AND WARWICK HOSPITAL. — The foundation stone of the new sanitary hospital for the Warwick Joint Hospital Board was laid at Heathcote on the 7th inst. by the Mayor of Leamington. The site contains about six acres and has cost about £1200. The hospital, which will provide accommodation for twelve patients, six of either sex, will, it is estimated, cost nearly £7000, including the necessary administration buildings.

THE UNITED GUYITE CLUB OF 1868.—The nineteenth annual meeting of this club was held at the Holborn Restaurant on Wednesday, Nov. 2nd, when Mr. G. S. Elliston of Ipswich took the chair. As next year will be the twentieth anniversary of the foundation of this club, the chairman expressed a wish, which was unanimously adopted by those present, that in 1888 every member should be present at the annual dinner, and it was further suggested that each member should bring a friend who had been educated at Guy's Hospital.

MEDICAL MAYORS.—The following members of the medical profession were elected mayors on the 9th inst.:—Alderman J. B. Stedman, Godalming; Alderman David Thompson (second time), Launceston; Alderman Clubbe, Lowestoft; Mr. W. Nettle, Liskeard; Major Adam Wilkinson, Shaftesbury; Alderman John Jones, Wrexham; Dr. Colmer, Yeovil; Mr. G. Booth, Chesterfield; Mr. William Rhodes (re-elected), Bridgnorth; Mr. J. C. Macaulay, Honiton; Alderman Samuel Farrant (re-elected), Taunton; and Mr. C. E. Baker (re-elected), Tenterden.

SMALL-POX IN SHEFFIELD.—The outbreak of small-pox in Sheffield has assumed serious proportions; as many as 100 fresh cases occur each week, and as the hospital accommodation is inadequate, it has been decided to erect temporary buildings a few miles outside Sheffield to accommodate eighty cases, these being in addition to the two existing hospitals. At the meeting of the Town Council on the 9th inst. it was decided to close the lending departments of all the free libraries in the town, to prevent the spread of the disease by means of infection brought by books.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

MEDICAL OFFICERS OF HEALTH AND GENERAL PRACTITIONERS.

Dr. Stewart.—A medical officer of health has no right in virtue of his office to visit patients suffering from infectious or other diseases, unless with the consent of the patients, or of those who represent them during their illness. There are occasions when it may be most desirable, and even necessary, for a medical officer of health to visit a patient, in order that he may advise his authority correctly; but these occasions are not ordinary ones, and when they arise it is of the utmost importance, both for the maintenance of the proper status of his office and the credit of his profession, that he should act in harmony with the medical attendants of the sick, on whom he is also necessarily dependent for valuable assistance. The current duty of a medical officer of health in the case of infectious sickness does not involve examination of the patient; it can be performed by accepting the diagnosis of the medical attendant, and by then seeking to discover the local circumstances favouring the sickness, and advising as to the best means of prevention.

A CORRESPONDENT, whose signature is undecipherable, but which appears like "*E. A. Stanford*," is referred to a paragraph in our last issue.

Mr. Lambert.—If samples be forwarded, they will have attention in the usual way.

SYPHILIS FOLLOWING TATTOOING.

To the Editors of THE LANCET.

SIRS,—At page 911 of your last issue, Mr. Grenville Moffet states, with reference to several cases of syphilitic infection following the operation of tattooing, "the only reference to this subject that I have been able to find is in Lancereaux's treatise &c." To those interested I would beg to point to Sections 1640:6 of both Medical Digest and Appendix, where several cases are noted; one paper published in THE LANCET nine or ten years ago, recording fourteen victims of syphilitic infection occurring in the practice of a celebrated tattooer.

I am, Sirs, your truly,

Boundary-road, N., Nov. 5th, 1887. RICHARD NEALE, M.D.Lond.

*** Much time and some of our space would often be saved if correspondents would consult Dr. Neale's valuable Digest in reference to the occurrence or record of pathological events.—ED. L.

COTTAGE HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly inform me where I can obtain copies of the rules of cottage hospitals, which I require as a model.

I am, Sirs, yours truly,

Great Yarmouth, Nov. 5th, 1887. ARTHUR WM. BLAKE, M.I.N.A.

THE GROWTH OF THE COCA TREE IN ASSAM.

THE *Monthly Magazine of Pharmacy* is informed by Mr. J. Buckingham, of Amgooria, Assam, who is now making a set of experiments on coca growing on his plantations, that the plants are all healthy, and have borne berries. He has gathered a small quantity of the leaves, and has had them dried and prepared like tea-leaves are for the market. This news is not unsatisfactory, as it is understood that at Darjeeling, where Mr. Hamstead of Seeyok and other planters have endeavoured to raise coca plants, the experiments have all resulted in failure, and this is generally attributed to the fact of the climate being too cold at certain periods of the year. It is quite possible that coca leaves raised in the East Indies, the plant being a native of the West Indies, may not possess the same valuable properties as those now used for the extraction of cocaine, but the experiment was certainly justifiable after the experience gained with regard to the cinchona tree, also transplanted from the West to the East, and yielding abundance of alkaloids in the Nilgheery Hills, if not elsewhere.

Alpha.—We think our correspondent can only recover against the person who requested his services; but he had better consult a solicitor.

C. E. M.—We cannot take the responsibility of recommending any particular work of a legal nature.

Mr. J. Abbott.—The address of the hon. secretary, Mr. A. G. Bateman, is 67, Longridge-road, S.W.

THE LOCAL APPLICATION OF CONDY'S FLUID IN SYPHILITIC GLOSSITIS.

To the Editors of THE LANCET.

SIRS,—The following case will perhaps prove interesting to readers of THE LANCET.

I was summoned to attend a man apparently about the middle period of life who presented the following appearance:—The lips were much swollen, and the mouth was quite full of a red ulcerated mass (from which unhealthy, malodorous pus was oozing), which on inspection proved to be his tongue. He was barely able to speak, and could with great difficulty swallow small quantities of liquid only. On closer examination I detected several deep fissures both on the under surface and dorsum, having indurated edges from half a line to a line in breadth. Offensive pus was welling up from the bottom of these fissures. One extended from within half an inch of the tip of the tongue for an inch and a half backwards, being nearly three-quarters of an inch deep. Another, on the right side, near the edge, ran parallel with the first, but was not so long or deep. A third extended downwards and backwards from the left side to the under surface. There were others smaller, some evidently healing, and more just beginning to ulcerate. The man complained of pain and soreness over the whole of the tongue and neck, but I could find no evidence of glandular involvement. He also suffered from "dyspepsia tonique," but was otherwise quite healthy. He informed me that he had been under several medical men, who invariably prescribed mercurials with tonics and applied solid nitrate of silver to the ulcers (some even recommended removal of a portion of the organ). This line of treatment was usually followed by alleviation of pain after some time and reduction of size, the fissures gradually lessening in number and extent, but no cure or permanent improvement. I prescribed Condy's fluid as a lotion, directing the patient to wash out the oral cavity every four hours with it, and gave the usual stomachic remedies. I called again in two days, and was much gratified to find the tongue appreciably diminished in size, the pus no longer offensive, but lessened in quantity, and that the patient could swallow fluids with greater ease. After an equal interval the patient felt much better; the dyspepsia was relieved, and at the end of ten days I noticed some of the fissures beginning to close, and could find no fresh ones. In three weeks all the fissures had healed, except the large central one and the one going downwards towards the under surface. These were, however, greatly reduced in size and depth, there being no marginal induration. At the end of two months he considered himself cured, and stopped the lotion, but in a fortnight after had to apply to me again, as an ulcer was beginning to appear far back at the root of the tongue. I ordered the same remedy as before, with like satisfactory result. He now always uses the lotion whenever any prodromal symptoms, such as pain or tumefaction, warn him. There has been no relapse for the past eight months. For diet I gave as much new milk as he could take, also meat juice, with one bottle of stout per day. I wish to add that I ceased to administer medicine of any sort after subduing the gastric trouble, though there was an obscure history of primary hard sore, but no secondaries, some fifteen years before.

I am, Sirs, yours faithfully,

Ferns, Co. Wexford, October, 1887. G. GREENE.

ETHER IN MIDWIFERY PRACTICE.

To the Editors of THE LANCET.

SIRS,—It fell to the lot of Dr. Rumboll and myself to deliver a primipara, aged thirty-four, by forceps after a ten hours' labour, during which much chloroform and ether were given. The child was apparently lifeless. Artificial respiration was kept up perseveringly by Dr. Rumboll, and the thorax was sharply slapped and sprinkled with hot and cold water, but with little result. We then injected ether subcutaneously, and improvement commenced. I do not see this use of ether mentioned in the midwifery books at my disposal.—I am, Sirs, yours truly,

Melksham, Nov. 2nd, 1887. S. GROSE.

WANT OF AN ASYLUM FOR INCURABLES IN LYONS.

DR. AUGAGNER of Lyons, editor of *La Province Médicale*, pleads for the establishment, by the local authorities, of a hospital or asylum for incurable cases, especially those suffering from cancer where an operation is impossible. He points out the miserable condition of such persons, who are necessarily discharged from ordinary hospitals after a few days' stay, these institutions being, of course, bound to reserve their beds for patients for whom something can be done. On going over the registers of the male patients of the Hôtel Dieu in 1886, Dr. Augagner found that 97 of a total of 6009, or 1·61 per cent., had been discharged as suffering from incurable cancer after a stay in hospital of from one to twenty-four days. Some few of these poor creatures are provided for by charitable religious institutions; but though the blind and the insane, and some other classes of incurables, have asylums to which they can go, the cancerous, who are perhaps the most to be pitied, have scarcely any refuge, and something more is, Dr. Augagner thinks, incumbent on the authorities than a small contribution to one of the charitable institutions alluded to, which is all that as yet they have been persuaded to grant.

Mr. John Wood.—It is not professional to advertise in the way described the price of advice and medicine either in one possessed of the qualifications of the Edinburgh corporations or of any other medical authority. Common law does not regulate professional conduct, but the bye-laws of the respective professional corporations.

Mr. J. Newlands Maclean.—It is usual to get 10*s.* 6*d.* for each attendance at the police-court. At each police-court there is usually a scale of fees, including medical fees, drawn up according to the instructions of the Home Secretary, by reason of the statutory power he possesses. Our correspondent cannot recover "unavoidable expenses" whilst attending assize.

F.R.C.S. & L.R.C.P.—The corps no longer exists. It was disbanded some years ago, and a local mounted police raised to replace it, the appointments to which are made by the governor.

PASSAGE OF FOREIGN BODIES THROUGH THE ALIMENTARY TRACT.

To the Editors of THE LANCET.

SIRS,—Several communications having been recently made to THE LANCET respecting the passage of foreign bodies through the alimentary tract, I think the under-mentioned case, which has lately been under my observation, possesses sufficient interest to be also recorded.

In June last a child, aged two years and a half, whilst playing with money, swallowed a shilling, and as it lodged in the throat the father endeavoured to get it back by the aid of his fingers; but failing to do so, he made use of a reverse method of treatment, managing to push it down with his index-finger, and a constant look-out for the passage of the foreign body was kept up. The shilling was not, however, passed, and four months elapsed, during which time the child became thinner, was irritable, and subject to many attacks of vomiting and bleeding at the nose. In October he had a violent attack after a meal, and with it brought up the lost shilling, which was much discoloured and corroded. From that day the child has rapidly regained its usual health and strength. I am, Sirs, faithfully yours,

Wisbech, Nov. 8th, 1887. WILLIAM GROOM, M.D. Cantab., &c.

"POISONING FROM THE USE OF SUBLIMATE SOLUTIONS."

To the Editors of THE LANCET.

SIRS,—In his third post-graduate lecture on "Practical Legal Medicine" Mr. Pepper in his concluding remarks wishes to draw attention "to a source of danger to life which, so far as I know, has not hitherto been noticed in the medical press. I refer to poisoning from the use of perchloride of mercury in the form of very weak solutions—e.g., 1 in 1500 or 2000." I would venture to draw Mr. Pepper's attention to a very able and interesting article read by Dr. Dakin before the Obstetrical Society of London on Dec. 1st, 1886, in which the author draws attention to the dangers of mercurialism in lying-in women. The article, which is entitled "Mercurialism in Lying-in Women undergoing Sublimate Irrigation," appears in full in the Obstetrical Transactions for the year 1886, vol. xxviii., pp. 261–307, while an abstract of the same appears in THE LANCET of Dec. 11th, 1886. The original article in the Obstetrical Transactions is well worth the careful perusal of all who are not acquainted with it, as it is, I venture to believe, a most valuable contribution to our knowledge of the subject.

I am, Sirs, your obedient servant,

Nov. 9th, 1887. H. T. R.

WATER-TIGHT CASES.

To the Editors of THE LANCET.

SIRS,—Messrs. Arnold and Sons are evidently not aware that their "new" invention, described in your pages of Nov. 5th—viz., water-tight cases—was made by us, and exhibited at the Philadelphia Exhibition, 1876, and for which we obtained a medal. Our case, however, is superior to Messrs. Arnold's, in that the projecting tongue is made of cork, which, being pressed into the groove, makes a much better joint than two pieces of metal can possibly do.—We are, Sirs, yours truly.

Great Portland-street, W., Nov. 5th, 1887. MAYER AND MELTZER.

Digitized by Google

THE LATE EDWARD THRING, M.A., AND THE OUTBREAK OF TYPHOID FEVER IN UPPINGHAM SCHOOL, 1875.

MR. ALFRED HAVILAND, in reference to an article which appeared in our issue of the 22nd ult., states that the fever first broke out in the school, and that it was not until thirty cases, with three deaths, had occurred amongst the boys that the disease appeared in the town. Mr. Haviland also states that it was owing to his objection that the school did not return to Uppingham immediately after the outbreak was checked.

Eudymion.—Yes, fairly strict. Under the circumstances described, it is very probable our correspondent would not be passed.

Mr. Maule.—No.

"SEA-SICKNESS."

To the Editors of THE LANCET.

SIRS,—In the numerous able articles which have appeared in THE LANCET lately on the above subject, I notice that an occasional feature of the evil is not noticed—viz., diarrhœa. During my experience at sea I met with three cases in which this was the prominent symptom, being unaccompanied by vomiting, although there was the usual vertigo, &c.

The first case was that of a chief engineer of long standing, who invariably in very rough weather suffered from a feeling of malaise with slight watery diarrhœa, which ceased with the bad weather. His appetite was good, urine rather lessened in quantity and clear. The only drug which had any effect on the diarrhœa was belladonna in large doses. His bowels were quite regular at other times.

The second case was a gentleman, aged twenty-five, who suffered from profuse watery diarrhœa with loss of appetite and a feeling of general depression whenever the sea was at all rough; no vomiting. Drugs were of no use.

The third case was a lady, aged thirty-three, single, who suffered so much from looseness of the bowels on any more than ordinary motion of the vessel as to be confined to her cabin for the greater part of the voyage (nearly two months). She was quite prostrate during each attack, took no food, and felt great dizziness on attempting to rise. Respiration was accelerated (about 20). She had no vomiting, and off the ship enjoyed good health. She was relieved by effervescing drinks (champagne), and was kept on a light diet when able to eat at all. Astringents had no effect, bromide of potassium seeming to be most useful. In port or during very calm weather she was quite well.

I think the theory of the churning motion of food in the stomach causing the attacks of vomiting is untenable: for (1) we get vomiting when the person has taken no food for some time before the attack; (2) a full stomach often stops the vomiting; (3) the continuance of the vomiting long after the stomach is empty; (4) the occurrence of vomiting in a perfect calm, and, as you mentioned in an able leader in THE LANCET of the 29th ult., the cases occurring before the vessel starts; and (5) cases in which the vomiting comes on without any sensations referable to the stomach at all—i.e., purely cerebral vomiting, several cases of which came under my notice, the affected persons having a good appetite and feeling quite well, with the exception of the sudden painless attacks of vomiting, which came on in bad weather at any time, lasting generally only a few minutes, and the ejected matter being, except after a meal, only colourless fluid. My theory is that sea-sickness is due to an unstable condition of the brain cells, chiefly affecting the neighbourhood of the vomiting centre in the medulla, and generally accompanied by hyper-vascularity of the brain. How this is caused by the ship's motion, and to what extent it is affected by the mental condition of the affected person, I will not attempt to explain. But the facts that the vomiting centre in the medulla, which transmits its impulses to the stomach, mainly by vagi and splanchnics, is in close relation to the respiratory centre; that we generally, if not always, find the respiratory movements increased in frequency during the attack; that we have generally increased blood supply to brain, as evidenced by throbbing of carotids, &c.; that the premonitory symptoms are usually vertigo, dizziness, &c., in a greater or less degree; and that all drugs which have any effect on the sickness are either cerebral or vascular sedatives—seem to point to the above theory being correct.

The cases of diarrhœa I ascribe to brain impulses passing to Auerbach's plexus (which governs the motion of the intestine), Meissner's plexus (which governs the secretion), and to the splanchnics (which greatly regulate the vascular supply of the intestine), and altering their normal functions.

As to treatment, I found no drug a specific, each case requiring treatment on its own merits. The only remedies which seemed universally applicable being rest in the recumbent posture (head to bow of vessel if possible), plenty of liquid, easily digested food, when it could be taken, and the free use of effervescing drinks (such as champagne).

I am, Sirs, yours truly,

R. MUSGRAVE WHITHAM, M.B.Ed.,
November, 1887. Late Surgeon, Ocean Steamship Company.

To the Editors of THE LANCET.

SIRS,—On reading the article on sea-sickness in your issue for Oct. 29th, I was reminded of a letter I had seen some time ago in one of the medical journals, in which the writer gave it as his opinion that the sea-sickness was caused by the movement of the boat throwing the intestines forward against the abdominal wall, and thereby suddenly stretching the sympathetic nerves. I do not see this particularly mentioned as one of the causes you give. It seems to me, however, a very plausible theory; for that position which is most favourable for a person to assume to prevent sickness—viz., lying on the back—is one which would, by causing the stomach and intestines to rest on the posterior wall of the abdomen, hinder any tension being put upon the sympathetics. I have known many people subject to sickness who could make a short passage by sea and avoid sickness during the voyage by lying all the time on the back. There are people also who feel sick when riding in a carriage with their backs to the horses, or seated the same way in a train; and I think it likely this may be explained by the above theory. Again, it is not improbable that the good effects of cocaine and the bromides may arise from their sedative action on the sympathetic system.

I am, Sirs, your obedient servant,

Banstead, Nov. 1st, 1887. WILLIAM HABGOOD.

"ANTIPYRIN IN MIGRAINE."

To the Editors of THE LANCET.

SIRS,—I am glad Dr. Berthold has alluded to the great value of antipyrin in migraine. My attention was first directed to this use of the drug by a paper by Professor Khomyarkoff and Dr. L'voff which appeared in the *Vrach* of Dec. 19th, 1885 (see abstract in THE LANCET of Jan. 30th, 1886); and, as far as I know, the credit of first suggesting antipyrin for the cure of migraine belongs to these Russian physicians. Since that time I have employed it with very great, though not invariable, success. Sometimes the first dose of fifteen grains has acted "like magic" within twenty minutes. In one inveterate case of periodically recurring migraine where the pain affected a single spot on the right parietal bone, the scalp over which used to become very tender, I was able for many months to give up morphia injections, antipyrin arresting the attacks almost entirely. In this case, however, there have been one or two attacks which no amount of antipyrin would relieve. In other cephalalgias which cannot be described as migraine, I have found antipyrin useful. Its employment in headaches and neuralgias due to ophthalmic affections was pointed out by Dr. Katsauroff (*Vrach*, No. 7, 1886; also see THE LANCET, April 10th, 1886). In many headaches of nervous, and in some which appeared to be of rheumatic origin, I have found antifebrine or acetanilide, in doses of from five grains to ten grains, very effective. I have not, however, been able to satisfy myself that it equal to antipyrin in true migraine. It would be of advantage if it were so, as it is far cheaper than antipyrin.

I am, Sirs, yours truly,

Woolwich Common, Nov. 7th, 1887. THEODORE MAXWELL.

COMMUNICATION OF RABIES.

To the Editors of THE LANCET.

SIRS,—In your issue of Oct. 22nd I notice that your Paris correspondent refers to "a precursor of Pasteur," and in your issue of the following week Mr. Lambert points out that herbivora can communicate rabies, but does not say to which class of animals. It may be of interest to some of your readers to learn that M. Reynault has caused rabies in sheep by inoculation from rabid sheep, also that Prof. Nocard of Alfort, in a letter to me last summer, stated that he had often given rabies of the horse to the dog, sheep, and rabbit by inoculation of the saliva. Prof. Duguid, of the Privy Council Office, informed me last summer that paralytic rabies was communicated to rabbits by inoculation of the medulla from rabid deer in Richmond-park, and also that true rabies was induced in a dog by a similar inoculation.

I remain, Sirs, your obedient servant,

Edinburgh, Nov. 8th, 1887. W. OWEN WILLIAMS, F.R.C.V.S.

"CHANGE OF AIR."

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly inform me where is to be found any good account of the reasons why "change of air" is of benefit?

I am, Sirs, faithfully yours,

Southport, Oct. 31st, 1887. EDWARD DAY MCNICOLL.

A Registered Practitioner, but never a Rejected Student.—We are unable to agree with our correspondent in his facts and inferences, whilst his proposals are surely quite impracticable. Examiners differ, no doubt; but there can be no question that in every one of the points referred to the examination system has vastly improved, and that, as a rule (with the fewest possible exceptions), those who pass and those who are rejected deserve their fate. No useful purpose will be served by publishing the letter.

Z.—We propose to publish an article on the question in an early number.

Dr. Myrtle.—Very soon.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Prof. Windle, Birmingham; Dr. Dickinson, London; Dr. Bristowe, London; Sir P. Bade, Norwich; Dr. Lindsay Steven, Glasgow; Messrs. J. Dewar and Sons, Perth; Prof. Owen Williams, Edinburgh; Messrs. Colnaghi and Co., London; Messrs. A. and J. Shaw, Grantham; Mr. Reginald Harrison, Liverpool; Dr. W. Fraser, Ashburton; Dr. Jas. Oliver, London; Dr. Groom, Wisbech; Mr. Lockwood, London; Mr. Biggs, Leicester; Mr. Young, London; Mr. J. Dixon, Kempston; Mr. Frask; Mr. F. Collins, London; Mr. Snell, Sheffield; Messrs. Harrison and Brass, Elgin; Mr. Fitzgerald, Folkestone; Dr. Battiscombe, St. Mary Cray; Mr. Cathcart, Edinburgh; Dr. Delvaille, Bayonne; Mr. Lawson

The Morton Lecture

ON

CANCER AND CANCEROUS DISEASES.

Delivered at the Royal College of Surgeons of England on Friday, Nov. 11th, 1887,

BY SIR JAMES PAGET, BART., F.R.C.S.

MR. PRESIDENT AND GENTLEMEN,—We may safely believe that Mr. Morton, in generously founding this lectureship, entertained the hope that it might lead to some distinct practical utility, perhaps even to the finding of a method for either the prevention or the cure of cancer and cancerous diseases. I hardly need say that we have none yet. Where or how may we hope to find one? We are bound to search everywhere and in all ways; but in one lecture I can speak of only one way, and it shall be that which seems to me the most hopeful. I think that we may justly hope to find a remedy in the constant careful study of the likeness of these diseases to others of which we already have means of useful treatment. We may be the more hopeful because the nearest likenesses of cancer and cancerous diseases are to two other groups of diseases concerning which there have been, in recent times, very useful additions to our knowledge. In one direction we have their likeness to the simple or innocent tumours, in the surgical removal of which the risk of life has been diminished, even while the range of operating has been increased; and in the other direction we have their likeness, which I believe to be much more intimate, to some of the specific and micro-parasitic diseases, a group in which there has been progress towards both preventive and remedial treatment. It is of this last relation that I propose especially to speak; and I shall try to show that it indicates the method in which cancer and cancerous diseases should be studied more thoroughly than they usually are.

Let me say that I purposely speak of "groups" of diseases. I would not attempt to define what shall be called tumours, whether innocent or cancerous, or what diseases shall be called specific. I would rather undertake, if it were necessary, to show the inaccuracy or insufficiency of any definition yet given. Definitions, if they are to be more than convenient helps to arrangements, belong only to sciences more exact than pathology can yet be. It is better, at present, to think of diseases as in groups with borders that are not clearly marked: or as of nations with ill-defined frontiers, and with inhabitants intermingling and even intermarrying. We may find typical examples of diseases as of peoples; it will be from such examples that I shall take my illustrations; and these typical examples we may describe and may call them by distinct names; and these names are convenient for nomenclatures and for registration, for indexes and catalogues; but we must use them very cautiously in the real study of pathology.

Cancer and cancerous diseases agree with the simple or innocent tumours, such as the fatty tumours and overgrowths, the fibrous and fibroid, the simply cartilaginous, and the like, in that they are all growths, structures growing with some degree of likeness to the natural structures of the body, especially of the part in which they are placed, but growing as if with a self-possessed power of maintaining and increasing themselves. With all tumours alike, this growing is so far dependent on external conditions as is that of the natural structures; but it is not, as theirs is, in evident adjustment to the plan of other parts, and is not subject to the general control which in health keeps each part in useful association and concurrence with every other.

This peculiar method of growing, purposeless, and, as one may say, selfish, is characteristic of both innocent and cancerous tumours, and it seems to indicate a very close affinity between them. It is rarely seen in any other disease than these, and some specific diseases to which I shall again refer. It is in some measure imitated in the cheloid growths of scars, and in the excessive callus sometimes formed in the repair of fractures; but these usually after some time cease to grow, even though they may show no sign of dying or degeneracy.

Another indication of the relation between the innocent tumours and the cancerous appears in that it is impossible to mark any fair boundary line between them. Between such as may be deemed typical examples of each—say a common fatty tumour and a cancer of the rectum or of the tongue—there seems no likeness, except that they all grow after the manner I have spoken of. In all the rest of their life-histories it would be hard to find two diseases more unlike, and yet the space between them and between all the innocent tumours and the cancers is filled with examples of intermediate forms; with sarcomata in all degrees of structural likeness to the one or the other, and with less or more of the characters of malignancy, the degree of malignancy usually corresponding with the degree of unlikeness to the natural structures. But this gradation is, as I have said, only what we find in all groups of diseases; and if, on the one side, we cannot exactly define innocent tumours from cancerous, so, on the other, we cannot define them from the many forms of mere overgrowths which are not distinctly purposive, such as fatty growths about the neck, enlarged prostates, thyroid glands, and the like.

The resemblances between the innocent tumours and the cancerous may seem to indicate so close relation that they ought to be regarded as of essentially the same nature. But I believe that an unlikeness indicating differences yet more essential may be observed in them, and it is expressed in our calling them severally innocent and malignant growths. Malignant is nearly synonymous with cancerous; and though the name is sometimes treated with disrespect, as being figurative and without scientific meaning, yet as an expression of certain qualities shown in the method and course of the diseases to which it is applied it is neither unfit, nor, I think, unmeaning. For the qualities which the name "malignant" indicates are far more distinctive, more surely diagnostic, of this group of diseases, than are the minute structure and chemical composition of the diseased parts, or even than the method of their growing; and in this is an example of what we must hold in the study of all diseases, for pathology is a part of biology, and not derived chiefly from the study of anatomy and chemistry.

The life-history of diseased parts and growths; the shapes that they assume; their construction; their changes as they grow, develop, or decay; the modes in which they extend, or ulcerate, or die; their products; their influence on adjacent and on distant parts, and on the whole economy—all these things, in so far as they are not dependent on evident structure and locality, are true signs of essential variation of material composition. They are the signs of the very nature of the diseases in which we observe them.

It is thus with morbid as it is with natural structures, and, indeed, with all living organisms. The characteristic shape, construction, and manner of life and work of each species, or even of each individual, indicate natural qualities and affinities more specific, and of which the manifestations during life are more distinctive, than are any others that we can discern. I would, therefore, not discard the name "malignant." It tells with emphasis, yet not falsely or with exaggeration, the general biological character of the whole group of cancers and cancerous diseases, and it may keep us in mind that it is by these biological characters more than by the histological or the chemical, so far as these can as yet be discovered, that their affinities to the innocent tumours on the one side and to the specific diseases on the other, may be judged.

In indicating the relations between the cancers and cancerous diseases and the specific diseases, I shall assume, as I did more than thirty years ago, when I was lecturing here on this same subject, that we usually mean by specific diseases those in each of which the phenomena of common diseases—that is, of such as might be produced by various injuries or external irritations in any healthy person—are modified in some constant and definite manner which gives them what we call specific characters. Every year's study since that time has made it more probable that what was then scarcely more than theory is now a sure general truth—namely, that each specific disease is due to the influence of a distinct morbid substance on some part or parts at which the characteristic signs of the disease can be and are manifested. Two conditions must coincide in each: the one general or

Digitized by Google

diffused in morbid material in the blood; the other local, in some part with which this material produces disease.

I use this vague term "morbid substance" on purpose that I may not pretend to definition or exact description. The reasons are, indeed, constantly increasing for the belief that each of many specific diseases is due to morbid changes produced directly or indirectly by a distinct species of minute parasite, a microbe, a bacillus, or some other vegetable of lowest organisation, yet specific—as specific as any of the species much more highly organised. I believe that micro-parasites, or substances produced by them, will some day be found in essential relation with cancers and cancerous diseases. Mr. Ballance and Mr. Shattock have, indeed, lately failed to find any; and if, in such a question as this, negative evidence could prove a negative, certainly theirs might make us hopeless. I would not be so, especially if workers so earnest and so skilful as they are will continue the search; but for the present it will be best to use such terms as morbid material, virus, or specific material, which, I think, we may be sure are at least not erroneous.

The specific diseases which we believe and generally know to depend on morbid materials in the blood are very numerous—the eruptive fevers, many of the diseases of the skin, tetanus, hydrophobia, ague, and many more. They may be vaguely arranged in groups, each of which may include those which are most nearly alike; and the group by which the conformity of cancers and cancerous diseases may be tested is one that includes, as its chief members, syphilis, tuberculosis, glanders, leprosy, and actinomycosis, each of which is known to have a distinct micro-parasite. Let me point out their most important general agreements. And, first, let it be observed that they are included by Virchow among tumours, under the name of granulomata; and I doubt whether they can be justly excluded from the list for any reasons which would not equally justify the exclusion of many of the cancerous diseases. Certainly, a tuberculous mass such as one may find in the brain, or a syphilitic gumma in a muscle, or, still more, an actinomycosis in the jaw, has more of the general characters of a tumour than any rodent ulcer has, or many cancers of the lip or tongue. It is at least evident that all these specific micro-parasitic diseases are, in their several measures and in some of their forms, morbid growths and self-maintaining. All agree in this general character; they differ from one another in that each has a definite, characteristic, and diagnostic method of growing, as shown in its shape and in its substance, both tangible and microscopic, and in its relations to the structures which it involves. In these respects they differ from one another about as much as any of them do from cancer.

Besides, in all these diseases, as in the cancerous, the morbid growths are prone to special modes of degeneration, of partial decay, and of death; and then they all tend to ulceration, each with a characteristic method, shown in the shape of the ulcer, the structure of its boundaries, and its mode of affecting the parts on which it encroaches.

And all the cancerous and the others alike are at some time infective; some by inoculation, all by invasion of adjacent parts, or by the transmission of materials, through lymph-spaces, lymphatics, or bloodvessels, to parts far off.

Now I venture to hold that likeness in characters so significant as these is evidence enough of essential likeness and of close affinity in all the diseases in which they are observed; and, therefore, that as we know that in tuberculosis, syphilis, leprosy, and the rest, there is for each a specific morbid material in the blood, so we should believe that there is at least one in cancer and cancerous diseases. The fact that it has not yet been found is not sufficient to prove that it does not exist.

We should observe here the same rule as we do in other groups of specific diseases. For example, among specific fevers, so-called, there is a similar general likeness, and they are regarded as a separate group or genus, call it what we will; and in this group there are many different fevers, each of which, though in many things like the others, has special and diagnostic characters, chiefly in the places, whether skin or glands or any others, in which it shows its local characters. Of many of these fevers, we know that each is associated with a different morbid material in the blood, a micro-parasite or whatever it may be; of the rest, we do not know this, but we do not doubt it; we are as sure of it as of anything in pathology not certainly known. So may we be, I think, that cancer and cancerous diseases are specific in the same sense as are those other diseases to which I have shown their general likeness. There are some unlikenesses between them: cancer cannot be inoculated, it is not contagious; but these are negative. I believe that there are no positive generic unlikenesses; and as to the differences among them, the diseases that are certainly specific do not differ more from cancer than they do from one another.

Let me note also one more likeness among all these diseases—namely, that, as we see them in practice, we cannot but observe degrees of conformity to what may be regarded as the typical forms of each. Just as I said that there are all degrees of transition from the innocent tumours to the cancerous, and to the mere overgrowths that are hardly abnormal, so are there all degrees of less or more malignancy. And, similarly, we may trace all gradations from the typical tuberculosis, through the less or more of scrofula, to what some call mere delicacy of health; or we may trace syphilis till we doubt its existence, or guess at it in some combination with scrofula or gout.

But now that I may illustrate the influence of different kinds of virus in the production of morbid growths, let me point to some of those occurring in plants.

The whole study of tumours may, indeed, find admirable illustration in vegetable pathology. For example, I think that some of the best evidences, even nearly the proofs, of the truth of Cohnheim's explanation of the origin of tumours, at least of the innocent ones, from portions of germinal tissue remaining undeveloped, may be seen in some of the xylomata or woody tumours which may be found on trees, especially on beeches and cedar-trees; for in these it is often evident, and always probable, that they have grown from buds, or "sleeping eyes," as they have been called, which have remained for a time dormant, inactive, enclosed within normal structures, and then have, as it were, awakened and grown, after a manner of their own, with good woody tissue, but separate and purposeless. Our museum has specimens of such tumours—oval or nearly spherical masses of hard wood, well defined, concentrically laminated, either lying just beneath the bark of the branch or trunk in which they have grown, or nearly separated and cast out. Some of them, like polypi or exostoses, have pedicles continuous with the proper wood of the tree, and some have little outstanding twigs or branchlets, outgrowths from the buds in which they themselves had their origin.

And if these and the vast number of growths of the same kind observed in plants may illustrate the apparently spontaneous production of the innocent tumours from germinal structures delayed in their development, so may galls illustrate the influence of a virus in exciting morbid growths. They may, indeed, illustrate both the conditions requisite for the manifestation of a specific disease—the specific morbid material and the part appropriate to its morbid influence.

Of these galls, which may fairly be called heterologous growths, as the xylomata may be called homologous, there are more than a thousand forms already known, and each form is produced by a different material, a different specific virus, as we may safely call it, inserted by a different species of insect in a leaf or some other part of a plant. The very nature of the virus which is usually inserted with the insect's egg is, I think, unknown; but so constant are its properties, and so exactly defined, that the specific characters of each insect are not more invariable than are those of the galls which it has made to grow. As we may describe the specific characters of each insect, so may we those of its appropriate gall; and so may we, therefore, speak of each form of gall as due to a specific virus. This is especially seen when different kinds of virus are inserted in similar textures, as when one finds three or four different galls produced by as many different insects on the same leaf.

The oak leaves which I have here show these facts well. I am indebted for them to Mr. Rolfe, of the Royal Gardens at Kew. Here are, as he has written, ten branchlets of the common oak, and their leaves bear, altogether, ten different forms of galls produced by ten species of insects; two, three, or four forms being on each leaf.

The only variation shown is in some spangle-galls formed on the leaf of a variety of the common oak, which are distinguished by their purple colour, but not by any apparent difference of structure.

Many of the galls are small, and may seem to you comparable with mere pustules formed of little more than disturbed natural structures; but they are not so; they are all outgrowths, in evident continuity with the natural

Digitized by Google

structures, yet different from them—often very different. All this is more plainly seen in the larger kinds of gall, each with its well-defined characteristic shape and construction, and its minute structures differing from the healthy structures with which they are continuous as widely as do cancerous structures from those of the parts in which they grow. And it may be observed that in all, whether small or large, the specific differences are marked by shape and pattern and other large characters more than they are by any minute structures as yet discerned.

I will not be tempted to go further in this intensely interesting field of pathology. I wish I could provoke some to pursue it, some who would study it pathologically with the same care and skill as Mr. Rolfe and others have studied it, as a part of natural history. It must suffice now to have shown in it how certainly each of a large number of morbid growths, each as heterologous, each as specific as that seen in any cancer or cancerous disease, is produced by the influence of an appropriate specific virus.

There is, however, one point more which I must mention, for it may help to show that even a well-defined virus can produce its appropriate disease only in some exactly appropriate place or texture. Each insect, with an instinct as unfailing as any natural law, deposits its egg and its virus in the leaf or other part of the very plant in which the right kind of gall can be formed. Each virus requires, as we may say, a susceptible and fitting place and substance; and this is a fact confirming what we believe in the case of many specific diseases, and, as I venture to say, in the cancerous. The two conditions must coexist—the specific material, microbe, virus, or whatever we may name it—in the blood, which will carry it to every part, and the one appropriate part, texture, or place in which this material can produce the disease.

Now this part may be so small or so ill-defined, it may seem so absolutely limited, as to give to the cancer when first found an appearance of being a merely local, a wholly local, disease; especially as the general health may be undisturbed. It may be called local in the sense that it is the only one locality in which it can be formed, but the analogy of the specific diseases gives reasons for believing that it would not have occurred in this place unless there were a specific material in the blood, which was carried to it; even as a gall would not form without the insect's puncture. And the like is evident in many specific diseases in which the presence of a morbid material in the blood is most certain.

For example, tetanus is due to a well-ascertained bacillus, and in the blood this, or some material produced by it, is carried to every part; but it seems harmless to all till, after, it may be, some considerable time, it affects some portion of the spinal marrow.

In hydrophobia there is a specific virus, inoculable, probably a microbe; it is everywhere diffused in the person or animal in whom it has been inserted; it is in the saliva, and, it is said, may pass even to the fœtus in a pregnant woman, or the milk of one suckling; and thus it may be during a period of good health, but at last it produces definite disease at the appropriate nervous centre.

In the sequelæ of fevers, where we cannot reasonably doubt that morbid materials remain in the blood, it is only in certain parts that diseases may be manifested. Thus, after scarlet fever it may be only in the tympanum or the lymph glands; or, after typhoid fever, in some cases only, in portions of the periosteum; in others, only in a testicle or in a small portion of one vein, or of the spinal marrow. These last are, indeed, very illustrative cases. After all the signs of typhoid fever have passed away, when the convalescence is established and all the waste and damage of the disease are being repaired—while thus, in respect of general nutrition, the health might be deemed above its average, we may find an acute inflammation of one portion of the periosteum of one bone. It is surely an evidence that that one portion was the only portion of the body in and with which the something in the blood could generate disease. It seems the more evident in the fact that sometimes the periostitis has appeared symmetrically on both the tibiæ. The two portions of periosteum symmetrically placed were identical in composition, as symmetrical pieces of the body often are; therefore both were similarly disturbed; no other part being exactly like them, no other was disturbed. In all the body nothing was susceptible of the disease except these two pieces.

Such facts as these deserve very thoughtful study, as evidences of the exceeding fineness of the differences among different parts of what seems to us the same structure. If a diseased process—say a syphilitic eruption—is evident on one portion of skin and not on another, it is an evidence that these two portions are not exactly alike. Whether the difference be in structure, or in composition, or in relation to the nerve force it may not be possible to tell; but there is a difference; they are not exactly alike, though they may appear so to every test but those of disease. The evidence is of the same kind as that by which a chemical test determines the difference of two solutions; only the test in pathology is far more delicate.

Now these considerations have a definite bearing on the question of localisation of cancer. There may be the appearances of perfect health; some have even thought that cancer is due to a kind of overflow of health; and, certainly, there is no greater fallacy than to think that, in its early stages, it is indicated by a cachexia; yet, with all this general health, the specific morbid material may be in the blood. If there be in the body a part, however small, which is susceptible of cancer, this may become cancerous; but we may fully believe that, if this one part had been as insusceptible as all the rest, the morbid material would have remained in the blood harmless and unobserved. Such things are sure in some of the specific diseases. Syphilis may reappear after years in which no sign of it could be found; or malarial fever may be for years dormant, till, with some accidental disturbance of the health, it may be renewed with its specific characters unchanged. In both cases we must believe that some morbid material remained inactive and apparently harmless in the body.

In a large number of instances we have, I think, no knowledge of the reason why the evidences of any specific diseases naturally appear in one part of the body rather than another; no knowledge of the reasons for the different powers of resistance or self-maintenance in different parts. We cannot tell why small-pox is especially manifested at the skin, or typhoid fever in Peyer's follicles, or tertiary syphilis in a piece of periosteum or muscle. But in all specific diseases, and in cancers more than in any, parts are rendered apt to become the seats of diseases after injury, or in degeneracies, especially those produced by long-continued irritation. Thus cancer increases in frequency with the advance of age and of senile degeneration. Its frequency in the breasts and the uterus before old age coincides with what may be deemed their early senile changes, when they cease to be capable of their proper purposes. So, too, all cancerous diseases are apt to form in parts congenitally defective; and still more they follow injuries, sometimes very quickly. More commonly still they appear in parts that have long been the seats of some "irritation," as we call it, as in the scars of burns, or in syphilitic tongues or gums, or cheeks irritated by bad teeth, or in lips irritated by pipes, or tongues by hot tobacco smoke. Similar to these are the soot cancers, and the petroleum cancers, and those of the abdomen and thigh, which are seen in Cashmir, in consequence of wearing a hot brasier over these parts.

Now, all these facts have led to our speaking of parts "becoming cancerous," and the term has, I think, been by some taken as implying that the beginning of a cancer is altogether local, and that the textures of a part may, as it were, of themselves, or through some common irritation or degeneracy, or in the course of syphilis or other diseases, change themselves and become cancerous—change, that is, their whole nature and mode of life from that which is common to that which is specific, or from one specific method to another. But this is far from being a fair deduction from the facts; for all these irritations and degeneracies are in many persons ineffective, and the facts observed are quite consistent with the much more probable belief that these degenerative changes only make the parts less able to maintain themselves, less able to resist the invasion of any morbid material in the blood which is brought into contact with them.

Here is, indeed, another likeness of cancer and cancerous diseases to the chief specific diseases. An injured part may become the seat of syphilitic disease, but this can be only in a syphilitic person; or of tuberculous disease, but only in a tuberculous person; or of gout in one gouty; and even small-pox may be confluent at an injured part, though discrete at every other. Thus, in diseases recognised as specific, in those that certainly have a specific morbid material in the blood, we recognise a local injury or irritation as making a part susceptible, or apt for the manifestation of the specific morbid changes. So should we think

Digitized by Google

when cancerous disease appears in such an injured or irritated part; and if we are to speak of such parts as becoming cancerous, it should only be with the understanding that they are becoming likely to be the seats of cancer if there be the other conditions required for that disease.

Really, to suppose that any previously healthy part could of itself, or in direct consequence of any ordinary change affecting it alone, so definitely alter its method of life, its shape and structure, its manner of growing and degenerating, as to become cancerous; and, still further, to suppose that all parts, however unlike in health, could change themselves into likeness as cancers—all this would be to assume more than can be matched in all the range of sure pathology or of natural history.

And the difficulty is not diminished by observing that the change is wrought in embryo structures. Embryo cells or protoplasms can no more of themselves change their destination, or by any common force be driven further from it, than any complete structures can. In so far as the destiny of germs and other embryo structures is not absolutely determined by inheritance, it is determined by their environment; they may be assimilated by force of the structures next or near them, and if these structures be cancerous the embryo structures may become cancerous; but to assume that such shapes and modes of life as we see in the tuberculous, the leprous, or the cancerous diseases, can be self-assumed by embryo structures or by protoplasms, is scarcely less than to assume that an embryo gland might of itself change its destiny; so that an embryo liver might become a lung.

I could, indeed, imagine that in the hereditary transmission of cancer there might be transmitted such a tendency to likeness to that part of a parent or ancestor which was cancerous, that the same part in the offspring might, as of itself, become cancerous; but even if this were sure, it would not explain the numerous cases in which the cancer in the offspring is not in the same part as it was in the progenitor, or those in which many members of one family have cancer in many different parts. To explain these we need to assume that there was transmitted a tendency to the production of the cancerous material in the blood; indeed, it would be hard and unfair to think that one tendency would be transmitted without the other. If both are transmitted, we may well suppose that cancer would form somewhere; but really one can be only guessing at questions such as these.

The fact of frequent inheritance is sure in this as in many other diseases, but its method is so mysterious; it is so utterly impossible to conceive the form or the material in which the impregnated ovum contains that which will become or be made cancerous, that it cannot be safe or useful to think that we can deduce anything from the bare fact. We are apt to speak of potentiality, tendency, and predisposition as if they were forces independent of matter or of structure; but when we try to think of the very things on which they depend, we find ourselves in a cloud-land of mystery, where the difficulty of discovering truth is as great as the facility of guessing.

I have limited myself to the pathology of primary cancer and cancerous diseases, and I shall not go far beyond it; for nearly all that happens in the history of secondary—or, as they are now wrongly called, metastatic—cancers, or of some that recur after operations, might happen as consequences of that which was at first an entirely local disease. If we could believe a primary cancer to be formed by any part in and of itself, then it would be easy to believe that this cancer would infect adjacent structures, and that materials would be carried from it in the lymphatics and the bloodvessels, and would grow and multiply in distant parts, and in them be centres for yet further infections.

But I hope that I have shown reasons enough for believing that primary cancerous growths are not merely local diseases, but require for their production at least the two conditions that I have spoken of. Once formed, the secondary diseases and much of all that follows, even to the inevitable end, may be due to transference of cancerous materials from the primary growths. But I do not think that all the secondary and yet later events can be thus explained. We have no reason for believing that the morbid material in the blood is always exhausted in the formation of the primary cancer, and it seems more probable that in some form this material remains or is renewed, and that to this, as well as to transference from the primary disease, the secondary and later changes are to be ascribed. I believe there are facts in the history of secondary cancers which cannot be explained by the merely mechanical process of penetration or of embolism. There are often evidences of other than mechanical relations between the primary and secondary. The organs that are most frequently the seats of primary cancer are very rarely the seats of secondary. The uterus seldom becomes cancerous in one who has cancer of the breast; still more rarely does the breast become cancerous as secondary to the uterus; and I suppose no one ever saw two cases of cancer of the face or lip or any part of the digestive canal following cancer of the tongue. Then there are the well-known cases of cancer of the thyroid, in which the secondary disease affects, as if by selection, the bones more often than any other part. And my son has gathered facts from the records of great numbers of cases of cancer which seem to indicate that the relations between the primary and the secondary seats of cancer may be compared with those which he found between the primary and secondary seats of suppuration in pyæmia. Certainly, some of those relations—such, for example, as that between the peritoneal and pelvic organs and the parotid gland—could not be explained by any mechanical embolism. Similar relations, I think, will be found between the primary and the secondary and later seats of cancer.

But I shall not discuss these questions; the main interest of the whole subject is in the biology of the primary cancer or cancerous diseases, and I hope I shall be deemed to have shown that in this, as in all the other characters of which I have spoken, there is so great likeness and so little unlikeness between these diseases and the specific ones with which I have compared them, that we may expect equal likeness in respect of the material on which they essentially depend. If it be so, then we may justly hope that by careful study, both clinical and experimental, we may find the morbid material, microbe, or ptomaine, or one or more of their products to which cancer is due. And if this be attained, then may we hope to be much nearer to a remedy, preventive or curative.

It would be easy to ask questions which this theory of the specific nature of cancer could not yet safely answer; to raise doubts which might seem to show it to be erroneous or insufficient. It may be asked, Why, then, is cancer not inoculable? Whence does its micro-parasite come? Why cannot it be found? Can one micro-parasite produce such various forms of disease? Where, in the unbroken series between innocent tumours and cancers, does the parasitic influence come in? I could not answer these questions. I could ask many more just like them; but I can remember that when I last lectured here on this subject, if similar questions had been asked concerning tuberculosis, leprosy, tetanus, or many other diseases now known to be dependent on parasitic or other specific materials in the blood, they could not have been answered; or, most probably, those which would then have been answered "No" would now be more correctly answered "Yes."

And now it may be asked, if all these things be in due time proved, what will the practical utility be; what the better treatment of cancer? I cannot tell. I promised only to suggest how best we might try to find out, and at least we may hope for more than is gained by the merely local operative treatment.

I should have tried to deal with this, but that the whole subject is so thoroughly and so admirably treated by my friend and former pupil, Mr. Butlin, in his recently published work on the "Operative Surgery of Malignant Disease," that I could not even in many lectures have taught so much as he does; but it is clear that, great as is the good that operative surgery may do when practised with the prudence which he urges, it does not do all we want; the disease returns even after complete removal of the diseased parts. All that is locally wrong may be removed, the local portion of the disease may be deemed cured, but something remains, or after a time is renewed, and similar disease reappears, and, in some form or degree, is usually worse than the first, and always tending towards death. It is true that, in less measure, the like of this may be observed in some of the cases of specific diseases which appear medicinally cured. Ague may have been cured, as we say, with quinine, or syphilis with mercury, and for years no sign of either may have been observed, but sometimes one will reappear in its old form, or as modifying some other disease. Especially we may see this in persons who have suffered with ague, or any similar kind of

Digitized by Google

malarial fever, or even without suffering from it have been exposed to the malarial poison. They may have been in good health for any number of years, but the ordinary changes following any considerable operation may bring out some dormant material; and all the characteristic signs of the fever may for the first time appear, or may be renewed, and may be cured, as we say, with quinine.

Still, we might well be nearly content if we could find a medicine as efficient against cancer as mercury and quinine are against syphilis and ague, especially as the recurrences of these diseases are less, not more, severe than the primary. Such a one we have not. Can it be reasonably hoped for? Yes, and the more so if we may count cancer among the specific diseases, for it is of some of these that we most surely have remedies more nearly complete than we have of any other disease whatever. The same commonly used of specific medicines may tell of this. There are none so definitely useful against diseases of any other kind; and, indeed, if we had to reckon cancer as a local disease, we should have to look for a different remedy for it in each locality.

But I can now only commend the study to my juniors. It must be both clinical and experimental, and probably the latter will be the more fruitful. If once the specific morbid material can be found, it may be dealt with as others generally like but specifically unlike it have been. But I will not guess how. I have tried to show by facts a right way to a good end: I will not now by guesses run the risk of pointing to a wrong one.

OBSERVATIONS ON THE

ANÆMIA OR CHLOROSIS OF GIRLS, OCCURRING MORE COMMONLY BETWEEN THE ADVENT OF MENSTRUATION AND THE CONSUMMATION OF WOMANHOOD.[1]

BY SIR ANDREW CLARK, BART., M.D., LL.D., F.R.S.,
ONE OF THE TEACHERS OF CLINICAL MEDICINE AT THE LONDON HOSPITAL, AND HONORARY FELLOW OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

EVERYONE experienced in the practice of medicine must have been often struck by the frequent occurrence of anæmia or chlorosis in girls between the ages of fourteen and twenty-four—that is, from about the time of the beginning of menstruation to about the time of the consummation of womanhood; and everyone acquainted with medical literature knows the great variety of names which has been given to this malady, the conflicts of opinions which have occurred respecting its nature, the confusion which reigns regarding its nosological position, and our complete and confessed ignorance of its causation. Many years ago, when studying the effects produced upon the body by the undue retention of the excretions and of the products of their decomposition, I came to the conclusion that this anæmia or chlorosis of girls was brought about for the most part by fæcal poisoning; and as the experience of later years has given increased probability to this view, I have at last ventured to submit it to the Society for discussion. As neither the time at my disposal nor the traditions of the Society will permit me to enter upon a historical and a critical consideration of my subject, I must confine my observations for the most part to the facts which constitute my personal experience, and to the more important reflections which they have naturally begotten.

The girl who is the subject of this anæmia, whilst often declaring herself perfectly well, looks extremely ill. Although very plump, she is very pallid. Her countenance has a wistful or a sad expression; the face is so puffed that its finer contour lines are effaced; the eyes are large and prominent, the conjunctivæ are white and watery, the pupils dilated, and the eyelids swollen; the lips are full, and of a pale purple colour; there is a slight varying flush upon the cheeks; the ears and neck have the hue of wax, and the hair is dry and thin. Although at first professing to be well, a slight cross-examination of the patient speedily elicits the fact that she complains of breathlessness and feelings of suffocation, of palpitations, noises in the ears, and throbbing headaches, of more or less constant pain in the left or in the right side, of languor or of malaise, and of frequent but fleeting storms of nervousness, irritability, and passion.

Passing to the objective and more methodical examination of a patient suffering from this form of anæmia, we shall find its presence manifested and characterised by the symptoms, which I proceed to enumerate. Beginning with the digestive system, one finds that the tongue, sometimes clean, is usually loaded at the base, indented at the sides, and watery; that the breath is tainted, and has on rare occasions even a fæcal odour; that the appetite is usually good, although capricious; that there are sensations of sinking between meals and of weight after food; that there is much intestinal flatulence of a disagreeable odour; that at one or other flexion of the colon, usually the left, there is more or less constant pain, extending to the back; that the bowels are either obstinately confined or inadequately relieved, and that the fæces, usually scanty, hard, dark, and lumpy, occasionally consist of showers of scybalous masses, embedded in an offensive mucus swarming with bacteria. Here I must pause for a moment to notice at further length two of the symptoms just enumerated as connected with the deranged digestive organs of anæmic girls.

In reply to questions concerning the action of the bowels, it is often said—and said accurately—that they are relieved daily, and it is often added, but added quite inaccurately, that in that respect there is nothing wrong. For it is quite certain that a daily relief may be an inadequate relief, and that with a regular feculent discharge there may be also a regular feculent accumulation. And in anæmic girls of the class of which I am speaking, I feel as sure as I can well be about anything of this character that inadequate feculent relief, or, in other words, feculent retention, is not only the rule, but the characteristic sign. To this point, however, I shall again advert at the close of my observations.

The second symptom which, occurring in anæmic girls, I wish to notice at further length, is the pain more or less constantly felt in the region of one or other of the right or left flexures of the colon. Occurring most commonly in the left hypochondrium, and rarely absent, the most diverse explanations have been offered of its seat and nature. For my own part, I have become convinced, both by the descriptions of patients and by my own inquiries, that the colon is the seat of this trouble. Some patients are so sensitive that they feel the passage of matters along the transverse colon, and they will explain that sometimes the passage being obstructed in the region of the left flexure, the obstruction is followed by an aggravation of the characteristic pain. Furthermore, when, for the relief of this pain, becoming at some time intolerable, an emetic of hot water is so administered by elevation of the patient's hips that it shall reach the transverse colon, the patient becomes conscious of the contact of the water with the painful part, and is also usually relieved.

The derangement of the genital organs occurring in the anæmia of girls has received an amount of consideration which neither the time and order of their development nor their intrinsic importance seems to me to warrant. In those disorders some writers find, or think that they find, the whole etiological relations of the disease. And Aitkin, indeed, defines chlorosis, the malady in question, as "that form of anæmia which occurs in the female at the period of puberty, and is to be classed among the functional diseases of the female organs of generation in the unimpregnated state."

One may sum up the genital disorders in chlorosis by saying that the menstrual period is usually regular; that the discharge is scanty, pale, and otherwise altered; that sometimes there is amenorrhœa; that on rare occasions the menstrual flow becomes excessive and irregular; and that almost always there is a leucorrhœal discharge. Now, for my own part, the more closely I have studied the time of the appearance of those disorders, the course which they follow, the effects which they produce, and the place which they occupy when found in other maladies, the less disposed do I become to regard them as the sufficient causal agencies in the evolution of this disease. On the contrary, I consider them to be secondary disorders, not primary results, not causes, and the outcome of antecedent and adequate conditions.

The condition of the urine, as far as it has been hitherto examined, teaches us but little. Usually it is copious, pale, acid, of low density, somewhat deficient in urea, uric acid,

[1] Read before the Medical Society of London on Monday, Nov. 14th.

Digitized by Google

and their congeners, occasionally albuminous, and always prone to speedy decomposition. Exceptionally, and this for the most part after the cessation of nerve storms, the urine is scanty, high-coloured, irritatingly acid, loaded with lithates and oxalates, and exhaling strongly urinous odour. The ordinary urine has always struck me as in several ways peculiar, and I suspect that when our chemistry of the ptomaines and leucomaines is further advanced we shall discover the cause of this peculiarity to be due to alkaloids absorbed from the alimentary canal and excreted through the kidneys.

The disorders of the blood and of the circulatory system developed in the course of this malady are numerous, varied, and important; and, together with the disorders referable to the nervous system, with which they interact, they constitute the characteristic signs of the disease.

Concerning the blood, it has been said by almost every writer of note in these days that there are but two essential changes: a little change, which is a paucity of blood discs; and a large change, which is an extreme penury of hæmoglobin. On these two changes, however effected, it is alleged that every alteration of tissue, every disorder of function, and every sign or symptom in this disease by which these alterations or disorders are manifested entirely depend. But I cannot accept this statement as either conclusive or complete. The clinical evidence of the existence of other changes in the blood is too clear and precise to admit of refutation. For example, as was first pointed out by Tuckwell of Oxford, a not inconsiderable percentage of chlorotic girls is subject to venous thromboses, and in at least one case of my own I have seen spontaneous clotting in the smallest arteries (inopexia).

Turning now to the symptoms of this anæmia as manifested through the circulatory organs, we find that the action of the heart, usually weak and regular, is sometimes tumultuous and irregular; that commonly a systolic bruit is heard within the pulmonary area; that rarely a bruit may be heard over any of the orifices, and even at the diastolic time; that the larger vessels are liable to attacks of local throbbings, and that slight compression of their walls elicits a systolic and sometimes also a diastolic murmur; that the pulse, varying in frequency, quickness, and force, is deficient in tension, and moderately full; that sometimes in circumscribed areas there are flashes of redness or of pallor; that now and then a finger, or a small tract of skin upon the body, will become suddenly blanched and remain in that condition for hours; that the venous system is flaccid; that one hears over the larger veins a continuous murmur of varying intensity like the buzziug of a fly; that the hand lightly laid upon the neck has conveyed to it a vibratory thrill; and that under emotional and other excitement the whole vascular system is capable of being roused into violent and perilous activity.

The blushing or blanching of organs which I have just adverted to, and which occurs in many different affections, is a subject of great clinical importance, and would justify separate and detailed consideration. But here, in reference to anæmia, I must content myself with saying that I have seen the blanching of a bit of skin followed by gangrene, and the blushing of kidneys followed by transitory albuminuria.

The respiratory disturbances in this anæmia are few, but strongly marked. The breathing, even in repose, is hurried, and it is painfully accelerated by emotion or exertion. The chest is always more or less oppressed; a dry cough is seldom absent; and sensations of suffocation are of frequent occurrence. Very rarely there is seen a little blood-stained mucous expectoration; and this, with a concurring dry, rustling character of the respiratory murmur, excites suspicions of approaching tuberculosis. But such suspicions are ill-grounded, for I have never seen the two affections—the chlorotic and the tubercular—concur in the same person.

In this malady the alterations of the skin are the most obvious. It is of the colour of long-kept white wax, lighter or darker at different parts; on the forehead it is of a greenish-white tint; on the temples and neck it is of a yellowish hue; about the lips and nostrils it is of a very pale purple colour; and about the eyelids it is like a withered autumn leaf. For the most part thick, dry, and cushiony, the skin is in some regions thin and soft and moist; in the axillæ and about the groins it is liable to profuse, and sometimes to rank, perspirations.

The nervous disorders characteristic of this chlorotic anæmia appear to be the results of an imperfectly nourished and constantly irritated nervous system. Its dominating conditions are an undue sensibility, irritability, excitability, instability, and debility. The patient suffers from a variety of disordered sensations, from sensations of heat or of cold, of numbness or of tingling, of loss of power or of internal spasms; and she complains of aches and pains, and weakness; of throbbing headaches, and of facial or pelvic neuralgias; of noises in the ears, and of disturbances of vision; of giddiness, and of disturbing dreams. But still more remarkable are the disorders manifested through perturbations of the higher nervous centres. At one time languid and indifferent, the patient at another time is interested and active. Sometimes capable of great temporary exertion, she is at other times exhausted by the slightest effort. Usually irresolute and capricious, she is occasionally obstinate and unreasonable. For the most part gentle and inoffensive, she now and then falls into a condition of insufferable irritability, or bursts into fits of uncontrollable passion. So variable is she in spirits that whilst to-day she may be sunk in the depths of despair, to-morrow she will be brimming over with mirth and laughter.

In view of this summary of the disorders accompanying the anæmia of girls, we must now proceed to inquire into the causes of the disease. As set forth by the chief writers of the time, they are of two sorts, the general and the special. The general causes are imperfect and improper food, deficient air, exercise, and light; overwork, especially of the brain; the dissipations of society; solitude and the absence of healthy amusements; disappointments and sorrows; secret impurities; digestive uterine and nervous disorders.

The alleged special causes of chlorosis are three in number. First, there is the theory of Virchow, which ascribes the malady to an imperfect development of the heart and larger arteries, associated with an original weakness of the formative power of the blood-cells. The second theory, advanced by Sée, explains the origin of the disease by the inability of the organism to meet the great reparative demands suddenly made upon it by the advents of menstruation and the concurrent increase of growth throughout the body. The third theory, proposed by Zander, ascribes the disease to the presence in the blood of unassimilable forms of iron, and alleges that this is owing to a deficiency in the organism of hydrochloric acid. It is held that by the use of this agent the iron is converted into assimilable forms, and that so the disease is cured.

It would be unprofitable to enter here into a critical consideration of these alleged causes of the malady under consideration, for the issue of judgment would surely be that they were inadequate to account for it. The malady occurs almost equally among the rich and the poor, among the generous livers and the plainly fed, among the cultured and the rude, among the idle and the occupied; and it seems to be independent of race or of nation, of climate or of soil, of mountains or of valleys, of seaside or of inland, and of country or of town.

Is, then, the problem of causation insoluble? I think not. And I even venture to express the opinion that if we submit to careful examination the conditions of life which accompany the appearance of this anæmia, we shall be able to discover in them violations of physiological laws common to every case, wherever found, and sufficient through the results of those violations to explain the essential characters of the disease. In the period between the advent of menstruation and the consummation of womanhood there arise physical, mental, and moral changes which greatly influence the girl's habits of life and thought. She becomes self-conscious, and enters into new relations with those whom she meets. She thinks of her appearance and tightens her waist. Afraid of getting fat, she stints herself in food, and eats of only dainty things. With her sense of modesty deepened, she is shy of being seen about the closet. Unprompted by nature, and perhaps disdainful of such affairs, she omits the daily solicitation of the bowels. And so at last it happens, through the compressed waist, the insufficient food, and the disregarded desire or the neglected trouble, that the bowels become either obstructed, confined, or inadequately relieved. In either case the fæces accumulate, are retained, and not only undergo changes in themselves, but provoke changes in the mucous membrane with which they are in contact. As one of the results of those changes, both chemical and biological, there are produced new substances, ptomaines and leucomaines, which are injurious to the organism, and which, absorbed into the blood, originate in girls of a nervous type of organisation those alterations of the constitution of

Digitized by Google

he blood which constitute the true pathogeny of this anæmia f girls.

Now, it is necessary to ask if this alleged cause of the nalady is adequate to the explanation of it? Well, it has een shown by Bouchard, in his lectures on Self-intoxication n Disease, that the poisonous activity of human fæces, ven in healthy men, is very great. And he concludes that here are formed throughout the intestines of an adult in wenty-four hours a quantity of alkaloids, which, if excreion were stopped and all were absorbed, would be sufficient o destroy life. It is, then, impossible to doubt that oisonous alkaloids are formed in the alimentary canal; that vhen excretion is seriously diminished they must be in some legree absorbed; and that, mixing with the blood and enterng the tissues, they must produce some sort of injurious ffects determined by the rate of absorption and the amount bsorbed.

And here arises the crucial question of this communicaion, Can any sufficient collateral proof be given that fæcal etention is not only adequate to explain the phenomena of his disease, but also that it is the true cause of it? Yes, here can, through an exposition of the means of cure; for he treatment which most speedily and effectually cures his disease is a treatment which by the use of tonic perients produces full and regularly recurring action of he bowels. With the suspension of this treatment the lisease recurs; with its resumption the disease again subides; and no treatment appears to be permanently successful vhich does not provide means for securing daily relief to the ntestinal canal. What are the details of this treatment?

I shall answer this question best by giving *au naturel* the lirections which I should prescribe for an ordinary patient. On first waking in the morning, sip a quarter of a pint of old water. On rising, take a tepid sponge bath; dry uickly, and follow with a brisk towelling. Clothe warmly nd loosely; see that there is no constriction of the body or f the limbs. Have four simple, but liberal, meals daily, rranged after this fashion: Breakfast, eight to nine—whole-meal bread and butter, with one or two eggs or some roiled fresh fish, or the wing of a cold chicken or pheasant, nd towards the close of the meal half a pint of equal arts of milk and tea, not infused longer than five minutes. Lunch or dinner, one to two—fresh, tenderly-dressed meat, read, potato, well-boiled green vegetable, and any sort of imple farinaceous pudding or of cooked fruit, preferably pple; drink one glass of Burgundy alone or in half a umblerful of water. Tea from four to five—whole-meal read and butter, with a cup of equal parts of tea and milk. Dinner or supper, from seven to eight—this should reemble the mid-day meal, but should be less in quantity. Nothing is to be taken after this meal, nothing between neals, and nothing but what is here set down. Walk at east half an hour twice daily, and as much more as strength nd convenience will permit. Retire to bed about ten, and epeat the sponging and towelling. See that your bedroom s cool and well ventilated. Lead a simple, regular, active, ccupied, purposive life; and do not notice or distrust ourself.

With such instructions modified according to individual eculiarities, I prescribe an old-fashioned ferruginous athartic, to be taken twice a day, about eleven and six. sually it is an acid mixture, designed somewhat as follows: Ferri sulphatis, gr. xxiv.; magnes. sulph., ℥ vi.; acid. ulph. arom., ℥ i.; tinct. zingiberis, ℥ ii.; infus. gent. co. el quassiæ, ℥ viii.; Fiat. mist. Sig. One-sixth part twice aily, about eleven and six. Occasionally this acid mixture roduces sickness, dries the skin, and is otherwise ill borne. n such cases I prescribe an alkaline cathartic mixture: 'erri sulphat., gr. xxiv.; sodii bicarbonat., ℥ ii.; sodii sulhat., ℥ vi.; tinct. zingiberis, ℥ ii.; spts. chlorofor., ℥ i.; nf. quassiæ, ℥ viii. Fiat. mist. Sig. One-sixth part twice aily, about eleven and six. Sometimes neither mixture grees, and then I prescribe sulphate of iron in pills with neals, and a saline aperient on first waking in the morning.

Upon the plan of treatment here described nine out of ten ases of this anæmia of girls recover their health in from one o three months; and if, when health is quite restored, one rescribes once or twice a week an aloes, myrrh, and iron ill, in doses just sufficient to bring about a moderate atural action of the bowels, the recovery will prove in all robability permanent. But upon this statement some of ny auditors will remark, "It is the iron which cures; t is not the aperient." That iron has much to do with the ure of the malady I admit, but I doubt if it plays the chief part; and I know that in numerous cases the use of iron, arsenic, and manganese unaccompanied by aperients has failed to cure. Furthermore, I have seen many patients who, having been treated in this manner unsuccessfully for months, speedily recovered their health under the influence of a ferruginous cathartic mixture and a regulated diet. And so clear and strong is the teaching of my experience upon the point under consideration that if in the treatment of this malady I were perforce limited to the employment of one sort of drug, the drug which I should choose for use would be an aperient.

And here I end where I began, by contending that the anæmia or chlorosis of girls arising in nervous constitutions with imperfectly developed sexual organs is caused for the most part, and in the first instance, by feculent retention and its consequences, and that the right as well as speedily successful treatment lies in the enforcement of a sound hygiene, the administration of ferruginous cathartics, and in the provision after cure for a daily and, as far as possible, a natural relief to the bowels.

The cardinal idea embodied in this communication, the idea of the evolution of diseased states from the retention in the body of its excretions and of the products of their decomposition, is one of wide application and of extreme importance in medicine. It has been often dealt with under the heavy discouragements of imperfect knowledge and unsound doctrines in past times; and in this Society, as well as elsewhere, I myself have endeavoured to call attention to the consequences and issues of pulmonary, cutaneous, and renal inadequacies. For a time, however, the wonderful results of bacteriological research engrossed our whole attention. But now that we are ceasing to be dazzled by their brilliancy and have had our visual powers restored, we can see that the ideas of auto-genetic and of bacterial infection are so closely related, and so curiously interact, that the true place of bacteriology in scientific medicine cannot be finally determined until the chemistry of all the devolutionary processes has been further advanced, and the relations of animal alkaloids and extractives to the genesis of pathological processes has been experimentally investigated anew.

Cavendish-square, W.

ON THE TREATMENT OF CANCER.

By PROFESSOR JOHN CLAY.

THE following cases of epithelial cancer have been treated during the past year, and as the disease has disappeared under the use of Chian turpentine they may be deemed of sufficient general interest to merit publication.

Epithelioma of the Uterus and Vagina.—Mrs. B——, aged fifty-five, residing in Devonshire, consulted me on Feb. 16th, 1887. She has never had children. She was operated upon twenty years ago by the late Sir J. Y. Simpson for contraction of the os uteri. Since that time she has not enjoyed robust health, but has not suffered from any special illness. Menopause two years ago. She has an anxious expression, is anæmic, but not cachectic. Six months ago she had a profuse purulent discharge, which continued for two months, when a severe hæmorrhage ensued lasting more than a fortnight. She had some pains in the back and in the lower part of the abdomen, but they were never very acute. Palliative treatment only was adopted until the gravity of the case was recognised by a consultant, who excised the os uteri four weeks before I saw her. The operation did not arrest the growth, which seemed to develop more rapidly afterwards and speedily involved the vagina. A few days before coming to me she consulted Mr. Knowsley Thornton of London, who confirmed the diagnosis of malignancy and expressed his opinion that the case was too far advanced for operative treatment; he thought it improbable that the patient could live longer than a month.

On examination I found that the posterior wall of the vagina at its upper part was occupied by a growth of the size of a walnut. There was also a nodule, which was more diffuse, and seemed to arise from the anterior wall of the vagina. These growths, which bled readily on manipulation, met in the centre, and entirely prevented any exploration of the uterus. The lymphatic glands were apparently free, and there was no bladder or rectal complication.

As there was no other plan of treatment open to her, I

Digitized by Google

recommended that the Chian turpentine should be pushed vigorously, the patient deciding to remain in Birmingham under my care. She was ordered one teaspoonful of Chian turpentine mixture, with resorcin, three times daily, to be rapidly increased to nine teaspoonfuls; the vagina to be syringed with equal parts of vinegar and water twice a day, and the growth to be painted two or three times each week with a solution of chromic acid (1 in 24). With the use of these remedies the growths diminished rapidly during the first two months, so that I was enabled to determine that the one mass did not proceed from the vaginal wall, as there was a projection of uterine tissue remaining, about a quarter of an inch in extent, proving that at the first examination there was considerable eversion of the cervix, and that when reduced in size the parts resumed a more normal position. The treatment was steadily continued, with occasional omission of the medicine, for two or three days consecutively. The vaginal growth entirely disappeared in about four months. The "stump" of the uterus was irregular, but did not present to the naked eye any appearance of being cancerous. There was no pain, and the slight discharge was singularly free from odour. At the end of six months the patient could walk three or four miles daily with comfort, and on a few occasions she drove upwards of twenty miles in an open carriage without experiencing fatigue. At the seventh month of the treatment she expressed herself as feeling well, and left Birmingham for Devonshire. Dusart's syrup was taken for the last three months. Mr. B——, in writing from home to me, stated that he had not seen his wife looking so well for fifteen years.

I had an opportunity of carefully examining Mrs. B—— a few days ago, when I found that the vaginal growth had entirely disappeared; the part it had occupied was covered with pale but healthy mucous membrane. The portio vaginalis was limited to a ring of healthy tissue about one-third of an inch in depth. The os was patulous, readily admitting the finger, which passed into the uterus about three-quarters of an inch. The interior was smooth, excepting posteriorly, where there was a nodule the size of a pea, which looked healthy, and appeared to be a portion of tissue which had escaped the cancerous attack. There was no discharge, and the patient was exceedingly well.

Epithelioma of Tongue.—Mr. S——, of Sheffield, aged forty-eight years, consulted me on May 20th, 1886. He was in fair health and well nourished. He stated that he had been suffering from an ulceration of the mouth for some time, to which caustics had been frequently applied. He had recently seen Mr. Jonathan Hutchinson of London, who pronounced the case to be one of epithelioma, and advised its immediate removal by excision. The operation, as represented to the patient, appeared to him an unusually severe one, especially as it did not promise to permanently cure him. Casually hearing of the case of Mr. M——, recorded in THE LANCET of Oct 16th, 1886, he determined to consult me.

On examination, a fungating growth was found in the floor of the mouth on the left side, involving the gum and the edge of the tongue for an inch and a quarter. The tissue surrounding it was very dense, the infiltration extending for quite half an inch. There were no sharp or irritating teeth, but the patient was a great smoker.

He was ordered Chian turpentine with resorcin, and to take one-twelfth of a grain of chrysophanic acid in pill every other night, also to have the growth painted with a solution of chromic acid (1 in 24) every other day. A gargle of perchloride of mercury (1 in 2000) was used as an antiseptic. This treatment was continued for four months, when it was found that two pieces had sloughed away from the anterior edge of the growth, and that the surface of the ulcer was covered by the characteristic grey slough usually present after the use of the mixture. The medicine was increased in quantity, and was well borne. The infiltration lessened, and the growth gradually disappeared—first from the gum,—being replaced by apparently healthy tissue. The floor of the mouth healed over, and the ulceration was limited on the tongue to a patch little larger in size than a sixpence.

At the end of thirteen months of the treatment the patient went to the seaside, where he caught a chill, and for the first time there was an enlargement of the left submaxillary gland, and a small abscess formed in the floor of the mouth. He was ordered half-drachm doses of the syrup of iodide of iron, and was directed to discontinue all local applications for a fortnight. At the end of this time the adenitis had disappeared. When two months more had elapsed the ulcer was only the size of a threepenny-piece. Mr. S—— has been able to attend to his profession during the whole of the treatment, and is now in excellent health. He patiently and perseveringly followed out the treatment, being ably nursed by his wife, to whom great credit is due for the punctual and careful manner with which she carried out my instructions.

Epithelioma of Nose and Face.—Mrs. S——, aged forty-five, a widow, consulted me on June 4th, 1887. Menstruates regularly; general health good. Has an epithelial ulcer on the left ala of the nose, and encroaching on the cheek. It began as a small warty growth two years ago, and readily bleeds during bathing, &c. Perforation was imminent. She had been under medical care almost constantly since the appearance of the disease, but without benefit, and as the affection was rapidly extending, she applied to me.

In this case I was desirous of trying the effect of the Chian turpentine alone. I therefore ordered her two teaspoonfuls three times a day, and to dress the ulcer with simple ointment. During the first six weeks there was no change in the appearance of the condition, and she began to despair of ever being cured. I told her, however, to persevere. After the treatment had been continued for two months the sore was covered with a greyish slough. At the fourth month two-thirds of the ulcer had healed, showing only a dark crust about the size of a fourpenny-piece. In two or three weeks the scab fell off, leaving the sore absolutely healed.

Epithelioma of the Uterus.—Dr. Hamilton of Finsbury-circus, London, has kindly furnished me with particulars of a case treated by him, and of which nothing was known to me until I received his report. The notes should be very highly appreciated, as the case is unique in regard to independent testimony, combined with a thorough and incontestable diagnosis. The communication is as follows:—

"May 27th, 1887.—The patient some five or six years ago had a small growth on the cervix uteri, which I pronounced to be epithelioma; it was hard, nodular, and attended with an irritating discharge, which was frequently bloody. After consulting a local medical man, who confirmed the diagnosis, I took her to Mr. Knowsley Thornton, who also agreed with us, and excised the growth, putting on chloride of zinc paste afterwards. I then had sections made of the tumour, examined it microscopically, and sent one to Mr. Thornton; it was undoubtedly malignant. The growth returned in about six months' time, and the patient again saw Mr. Thornton, who stated that the cancerous material had now invaded the body of the uterus, which was fixed within it, and that this time he could do nothing without he scraped it all away from the interior. This, however, he did not advise at all strongly; he just took off what he could on the vaginal part of the cervix, and put on some chloride of zinc paste as before. I then made up my mind to try the Chian turpentine, and I kept her on that and the compound sulphur pills for about a year; the symptoms gradually disappeared, the discharge and blood lessened, until, I may say, now there are no symptoms whatever indicating a return. Now this was a case of undoubted epithelioma, as shown microscopically; and I have, as you may imagine, now the strongest possible faith in the efficacy of Chian turpentine."

Birmingham.

THE CLIMATIC TREATMENT OF PHTHISIS IN THE STATE OF COLORADO.

By M. CHARTERIS, M.D.,
PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, GLASGOW UNIVERSITY.

FROM a very early period in the history of medicine we learn that change of climate and change of air have been considered as remedial agents of great efficacy. Supported by custom and fortified by experience, this opinion was always acted upon, although there were no substantial reasons given for doing so. In fact, we may say that until Sir James Clark's book was published on the "Influence of Climate," in 1829, no definite ideas had been entertained, and no rules had been laid down, for the guidance of physicians in selecting a climate for any disease. Sir James Clark's treatise dealt with the influence of climate in the prevention and cure of chronic diseases, more especially of the chest and digestive organs. The book is full of wise reflections

Digitized by Google

gathered from a large experience, and is couched in anguage forcible and plain. It may be read at the present lay with great advantage, although the views he expresses as to tubercle may be considered, in the light of this scientific age of bacteriology, as somewhat antiquated. Since Sir James Clark's time much has been learnt as to the nature of tubercle, its causes, its development, and its progress either to recovery or to death. No one doubts now the utility of a climatic change in phthisis, but opinions vary as to the place that should be selected. It may be said broadly and truly that no climate possesses specific powers, and hence we find some advocating a warm, moist atmosphere amid flowers and sunshine, while others prefer one amid snow and ice. No general rule can be laid down. The decision in each case must to a great extent be guided by the age, the sex, the mode, and rank of life of each consumptive patient. These considerations can never be undervalued by anyone whose advice is sought. Yet while individual cases must be duly weighed, I think the tendency of the present medical views gives precedence in a case of phthisis to a dry rather than a moist atmosphere, a high altitude to a low one. And if we look at tubercle briefly from its pathological aspect as to what it is and how it grows, we can better understand how the preference is given.

Nature of Tubercular Change.—Avoiding all controversial points as to its etiology, being primarily bacillus or otherwise, we may state that tubercular change usually begins in the walls of the smallest bronchi, generally in one or two circumscribed spots, and in the great majority of cases in the apex. The tubercular infiltration thus begun in the bronchial wall spreads gradually to the periphery, establishing tubercular peribronchitis, in which are noticed "cheesy nodules," which at first are grey and later yellowish. The adjacent nodules run together; a little irregular excavation succeeds, which is the first beginning of the formation of a cavity. With the disease of the smaller bronchi the alveolar tissue of the lung is also affected, and partial lobular pneumonia results, which from its tubercular character becomes caseous. The alveolar walls are also diseased, and the destruction of the cheesy tissue results in the further formation of cavities, or in diffuse caseous pneumonia. With these destructive processes there is a tendency towards circumscribing the disease, thus limiting its growth and causing healing. New connective tissue forms round the tubercular infiltration, especially where there is already destruction of tissue, and this chronic interstitial process leads to contraction and the formation of a cicatrix. In chronic phthisis the conservative contractile changes evidence that the tubercular process may heal. This tendency to heal may, however, be baffled by the infectious material, being carried into other bronchi, and in this process the tubercle bacilli are important agents. So new tuberculosis is set up, and the disease is constantly extended.

Influence of Climate on Tubercle.—It seems evident from this short pathological survey that the true treatment of phthisis once begun is to assist nature in limiting the process of the disease. Climatic treatment is obviously suggested, and the nature of that climatic treatment will now be considered. Tubercle cannot live without moisture. A moist air nourishes its growth, a dry air tends to destroy it. The breathing of pure, dry air, not by fits and starts, but constantly, is what we have to desire, and the question is now narrowed to this, Where can this pure, dry air be found? Undoubtedly in Europe we find this in winter at Davos Platz, but the unfortunate facts stare us in the face that phthisical patients can only remain there during the winter, and that they must remove to some other locality when the snow melts. The healing process, thus commenced but not finished, is again tried by a different atmosphere, not dry, but variable and moist, and again the disease, not in all cases, but in many, resumes its fatal course. Davos Platz has not therefore the elements of a permanent cure, and we must look to other places where the conditions are more favourable. It appears to me that we have these conditions in the air of Colorado at certain stations where the altitude is great. Here we have at Colorado Springs a charming health resort at a height of 6000 ft., situated six miles from Pikes Peak, which towers up to the extent of 14,000 ft. Manitou Springs (altitude 6700 ft.) lie at the base of this mountain, but the circumscribed position and the lack of a free current of air and afternoon sunshine render it not such a desirable residence during winter as the Colorado Springs. Passing further on in the same range of the Rocky Mountains we come to Denver, with a population estimated at 80,000, and an elevation of 5000 ft. This town is well built. The streets are wide, the hotels large, the shops attractive, and the environs interesting. In none of the places mentioned are there cramped surroundings. They are not hemmed in by mountains, but stand on elevated plains, over which a pure, dry air ever sweeps. The seasons are marked by no extreme climatic vicissitudes. There is no extraordinary heat in summer, and no excessive cold in winter. The average summer heat is 70° F.; the average winter cold is 9·5° F. Winter steals upon autumn with no marked change. The snow that falls rarely rests more than twenty-four hours on the ground, and leaves, when melted, no slush under the foot. In no season of the year is there a prolonged rainfall, for the whole amount annually only reaches fifteen inches. The principal rainfall is from April to the middle of October. The rain is never continuous, only falling at intervals in heavy showers lasting rarely more than twenty or thirty minutes. The medical officer of health of the city of Denver has kindly forwarded to me a summary of the monthly meteorological reports for the last ten years, and statistics as to the mortality for five years. From the meteorological report I learn that during the periods mentioned the mean temperature of June was 67·9°, of July 70·0°, of August 68·6°. During the same months the total precipitations for June was 1·4, for July 2·4, and for August 1·4. During the same months there were no foggy days, and only twice in each month were there cloudy days, the other days being clear and fair. During my stay at Denver I noticed the diathermancy of the air, or the increased facility by which the sun's rays are transmitted through the attenuated air. This tends, according to Dr. Denison, to an increase in the difference between the sun and shade temperatures, according to the elevation, in the proportion of 1° F. for every rise of 285 feet. Though the sun in August was hot in the open, yet in the shade during the day and in the evening it was always cool.

Action of the Colorado Climate on a Healthy Person.—Previous to describing the action of the climate of Colorado in disease, we shall briefly allude to its influence on a healthy person. A marked influence is exerted on the circulation. The pulse is quickened, and the beats of the heart are audible when standing still. This increased cardiac action sometimes gives rise to considerable anxiety to new comers, and they should be informed that in the course of a week these disagreeable impressions will cease, and the circulation will become normal. During the continuance of this increased action of the heart the nutrition of the brain is markedly disturbed. There is little desire for sleep at the usual hour for going to rest; and sleep, when it does come, is restless. The slightest noise awakens, and dreams, vivid but not very pleasant, are associated with incomplete repose. All people suffer more or less from sleeplessness on their first arrival in Colorado, but the condition is aggravated in females, owing probably to their more delicate and sensitive nervous system. Full, deep inspirations are taken which expand the lungs, and the expirations seem less prolonged than in a low latitude. The keen air leaves the mouth dry, and this sensation, appreciable at an elevation of 5000 ft., becomes very marked at a higher altitude. My experience on this point was peculiar, and to me unexpected. I proceeded from Denver by rail to Silver Plume, a small village up the gorge of the Rocky Mountains. When I arrived there at midday, as the day was not warm, I started with the intention of taking a good long walk. But the effort was fruitless, for in a short time I found my mouth dry, my voice hard and croaky, while a panting indescribable "all-overish" sensation replaced the easy respirations of health. I was glad to rest and wait patiently for two hours until the train arrived to take me to Denver. The skin never feels moist. Yet there must be considerable perspiration, for the urine markedly diminishes in quantity, although the amount of fluid taken is equal to that drunk at an ordinary altitude. The appetite is keen, and food is enjoyed with relish and easily digested. These are the chief points of difference I detected, and physicians at Denver and Colorado Springs told me they were by no means singular.

Action of the Climate on the First Stage of Phthisis.—We shall now turn from considering the influence of the climate of Colorado in health, and speak of its action in tubercular disease of the lungs. We will suppose a case of phthisis at home, where weakness and loss of flesh have been followed by expectoration, and an increase of the evening temperature

Digitized by Google

to 99° F. If hæmoptysis existed, we will presume that for the present it is checked, for unless this is the case a sea voyage from our country undoubtedly tends to bring it back. The patient leaves home, say, at the end of August, and arrives at Colorado fourteen days afterwards.[1] His first step on arrival is to secure, according to his means, suitable rooms, and these can be had in private houses or hotels at terms varying from 10*s.* to 15*s.* per week; if with board from 24*s.* to 48*s.* His next step should be to consult a medical man acquainted with the climate and of good professional standing. The advice given to him will in all probability be this: To be out of doors all day, and to take systematic exercise; to avoid night air, and to retire to rest early. Above all, it will be deemed advisable to insist on the patient considering himself or herself an invalid, and to take no liberties either in food or drink, and to have amusements in which there is nothing to excite or to agitate the nervous system. Rigorous self-control must be put in force, and the professional mandate must be strictly and literally obeyed. Returning health makes this difficult at times, and restraints may be considered irksome. Yet a false step may retard all the improvement happily begun. Sometimes, on account of this, a cold is caught and broncho-pneumonia develops, the prognosis of which is very grave, for all acute inflammation of the respiratory tract in high altitudes tends to assume a serious form. After six months, in all probability, the patient will feel well, with no cough, no expectoration, no weakness, and with a temperature which is normal. The bodily weight will have increased, from the bracing air necessitating the taking of more food and assisting the proper assimilation of it by the system. Shall the patient now return home? Undoubtedly not. The risk is too great. There is arrest of the disease but no permanent cure. A moist, damp air will certainly bring it back in an aggravated form. Consequently the advice is generally given that the patient, if a man, should proceed to a ranche in the latter month of spring. There board varies from £2 to £2 10*s.* per week; but if the man can, and is willing to work, he will find no difficulty in obtaining employment. When the hay season commences, wages are paid to labourers at the rate of from four to six shillings a day with food. And on the same or increased terms he can earn his living as a cowboy, pursuing, by daily horseback exercise, the method of treatment, which Sydenham considered "as certain a cure for phthisis as quinine was for ague." From all I can learn, the cowboy's active life is one characterised by good fellowship, primitive manners, and redundancy of health. There are also opportunities for those who like this out-door life not merely earning a living, but of making money. The field is large, and the chances are many. If this life is not congenial, then in a town like Denver, with 30,000 inhabitants and increasing rapidly, he has a prospect of going into business with good hope of success.

(To be concluded.)

SEVEN CONSECUTIVE CASES OF LAPAROTOMY.

BY W. BALLS-HEADLEY, M.A., M.D. CANTAB., M.R.C.P.E.,
HON. PHYSICIAN TO THE WOMEN'S HOSPITAL, MELBOURNE, VICTORIA.

CASE 1. *Multilocular Ovarian Tumour; Ovariotomy; Recovery.*—Mrs. H——, aged thirty-nine years, was first seen by me in November, 1877, when I treated her without operation for double laceration of the cervix and retroflexion. In May, 1880, she had an enlarged ovary posterior to the uterus and no retroflexion. In February 1881, the tumour was exceedingly hard to the feel. Mr. Rudal gave ether, and I aspirated one pint and a quarter of clear, straw-coloured fluid, which was one-third albumen, and contained Drysdale's cells. In October I drew off six ounces more, and decided, on its refilling, to remove the cyst by the vagina, but did not see her again till March, 1886, when she was confined to her bed. A multilocular ovarian cyst occ pied the abdomen to the ensiform cartilage and w moderately prominent; but she was rendered ill more l the occupation of the pelvis by a solid mass, which appea to have developed from the original pelvic cyst, than l the abdominal enlargement. Her pulse was 120, thin; a her temperature was from normal to 100°. She was ve thin, and her face drawn.

On March 29th, Dr. Burke saw her in consultation wi me, and on the 31st he administered ether and methylen and, assisted by Drs. Le Fevre and Lalor, I operated. A incision two inches and a half long was made between t umbilicus and pubes, and the various cysts aspirated into two-gallon bottle, as is my custom, when the pelvic tumo was with some difficulty extracted. The left ovary was al cystic, and was removed. The pedicles were tied with sil with a Tait's knot. The wound was closed with silver an horsehair sutures. The operation from beginning to en occupied twenty-five minutes.

She was treated with a pill of powdered opium (one grai occasionally when in pain and awake. The temperature di not exceed 100°, nor the pulse 100. On getting up, th uterus was retroverted, and a severe drag on the abdome occurred on walking, apparently from an adhesion of t left pedicle. A pessary presently relieved this, and sh became quite well.

CASE 2. *Multilocular Ovarian Tumour; Ovariotomy Recovery.*—Miss P——, aged forty, a patient of Dr. Snow ball, who called me in consultation, was in bed for six week with rheumatic fever when eight years old, and since the has been subject to rheumatic pains. Has for years ha piles; worse the last year. In December, January, an February had low fever and cough. In March noticed lump in the lower abdomen, when she was much increase in size, and since then has become very much larger. Ever day has pains like needles or shooting at the lower righ abdomen, or from right to left, and has got thinner. Th catamenia has always been regular. Is 5 ft. 8 in. high, thi with a prominent abdomen. There is a tumour extendin from the pubes to half-way between the umbilicus an ensiform cartilage, occupying the whole of the right sid and three-fourths of the left; doubtfully fluctuatin apparently not; dull on percussion, but with resonance i the right groin, and less in the left. The hymen is entir The os uteri dimply. The sound passes in the normal direc tion through the cervix to the fundus two inches and a hal Pulse 120. There is a systolic bruit at the base and apex The rest of the organs normal. On exploratory puncture, straw-coloured fluid gave Drydale's cells.

On August 5th, assisted by Drs. Snowball and Fishe Dr. Burke kindly administering ether and methylene, I mad an incision two inches and a half long midway between th umbilicus and pubes, and found a very multilocular tumour the right ovary, which was aspirated as usual. The left ovar which was cystic, and as large as a hen's egg, was remove The pedicles were tied with fine silk in a Tait's knot, an the wound closed with silver and horsehair sutures. Th operation occupied thirty-five minutes. No sedatives w given, but on occasions sulphate of magnesia or calom after Lawson Tait's method. The temperature did exceed 100°; the pulse from the cardiac affection vary from 100 to 120. There was some difficulty from constipati from the tenderness of the piles, and a contracted sphinc ani, while the hymen prevented vagina-rectal assistan The recovery was uninterrupted, and she was up on sixteenth day, and has been quite well except for the pi which Dr. Snowball and I lately removed.

CASE 3. *Multilocular Ovarian Tumour, with Twi Pedicle; Acute Peritonitis; Pregnancy; Ovariotomy; Ab tion; Abdominal Abscess; Recovery.*—After a series of succe ful ovariotomies, the question arises, why should fatal c occur in future? The mode of avoidance of one class them is here indicated. Mrs. S——, of South Melbourne, h had two children, the last three years ago. The catame had ceased on May 24th. On August 26th she was taken and Dr. Barker found her suffering from acute perito and constant vomiting. Dr. Brett also saw her. I Dr. Barker in consultation on Sept. 2nd, when her temp ture was 102° and pulse 120. The abdomen was gre distended, and the skin brawny; resonant in the hypoch dria, dull in the flanks. The diagnosis was that, in absence of other apparent cause for the peritonit tumour had burst or become twisted. She took one g

[1] The railway rates from New York to Denver are liable to frequent fluctuations; at the present time they are as follows: First class, £10 7*s.* 11*d.*; second class, £9 11*s.* 3*d.*; emigrant, £8 14*s.* For the passage from Glasgow to New York by the State Line the rates are: Saloon, £17 7*s.*, or £8 8*s.*; and steerage, £4. The rates by the Anchor Line are from £8 8*s.* to £10 10*s.*

Digitized by Google

f powdered opium in pill every four hours when awake, nd had linseed poultices applied. On the 4th the tempera- ure was 100°, pulse 100, the abdomen more lax, and a umour could be felt reaching from the pubes to half way etween the umbilicus and ensiform cartilage, central, eely fluctuating; neither fœtal heart nor placental bruit ould be heard. On the 6th the tumour was more distinctly lt. We decided to admit her at once to the Women's ospital for immediate operation, on the diagnosis of varian tumour, with twisted pedicle and pregnancy of bout three months and a half.

In the hospital on Sept. 6th I drew off with a fine needle ne ounce of light red fluid, which gave atrophic blood cells nly. At a consultation of the hon. staff opinions as to the ondition varied, and in view of the unsatisfactory micro- copic examination it was determined to wait. From the th to the 10th, the morning temperatures were normal, the vening temperatures varying from 98·8° to 99·8°; pulse om 96 to 100. Adhering to my original opinion, and guided y the experience of former cases, on Sept. 10th I again rew off an ounce of fluid, which was of a deeper red than efore, and full of Dysdale's cells. A sound was gently passed pparently to the fundus uteri (four inches), and a con- ultation was called for the 12th, with a view to an immediate peration, which was held and so determined.

On Sept. 13th the operation was performed in the presence f Drs. Barker, Doyle, Forster, Meyer, and Workman, Dr. urke giving ether and methylene, Drs. Fetherston, Rowan, nd Hooper, the resident surgeon, assisting. The abdominal alls had many bleeding points, which were compressed ith Spencer Wells' forceps. There was general peritonitis. he tumour was seen to be of a dirty purplish-black colour. he contents (one gallon and a half of a purple colour) were spirated with a large trocar into a two-gallon bottle. The umour was on the right ovary, was universally adherent, but adily separated, and similarly the intestines; the pedicle as occupied by clots distending it irregularly as a flattened usage, and so extending to the right iliac region, to which was closely adherent. This had previously burst, and had us apparently caused the original peritonitis. It left a uish-grey clot surface close to and apparently attached to testine, so that it could not be removed; it was sponged clean as possible. Below this expansion the pedicle was ghtly twisted, deep down, close to the uterus, and was ith difficulty tied with a Tait's knot, whence there was no emorrhage. A large piece of semi-gangrenous omentum, hich had been adherent to the tumour, and which bled at any points, was similarly tied and removed. Much oozing curred from the previously adherent intestine high up, ep, close to the abdominal aorta, which pressure did not op. Sponges squeezed out of a one to four solution of quor of persulphate of iron produced more but not quite rfect effect. The oozing was from very numerous but ex- edingly fine points in the peritonitic surface of the lately herent intestine. The left ovary was found enlarged to e size of a hen's egg and cystic, and its Fallopian tube uch enlarged and intensely inflamed. Both were tied se to the uterus with a Tait's knot and removed. Great re was taken in thoroughly cleansing, and the cavity was shed out with pure warm water. In view of the intense ngestion and slight bright oozing from the untiable in- stine as mentioned, as well as the dirty clot surface istent on the right side, a curved glass drainage tube reach- g to Douglas's space was introduced. The uterus reached to ove the pubes, was apparently pregnant three months d a half, and was much congested. The wound was then sed and dressed with absorbent cotton. At 10 P.M. the lse was 96 and the temperature 98·5°; and, as she was ry restless, a suppository of a quarter of a grain of rphia was introduced into the vagina. No more sedatives re given.

The patient progressed well, and her temperature did not ceed 100°, except when a large stool descended and ed the rectum, whereby some strain was, no doubt, put the newly coherent surfaces; seram came through the inage tube, which was removed on the second day, and ne matter subsequently through the upper end of the und. On Sept. 20th she had a vaginal red discharge like nstrual fluid. On the 22nd she became convalescent, and temperature normal. On the morning of Oct. 5th she l pains, and the umbilical cord was found in the vagina, but temperature and pulse were normal. It was impossible her to carry the child to term in view of the universal hesions in the abdominal cavity. At 4 P.M., the tem- perature rising to 99·5° and the pulse to 108, it was deemed necessary to assist her, and under methylene I delivered her, piece by piece, of a fœtus with breech presentation, which had been dead some two or three days, with con- siderable difficulty on account of a contracted uterus. The placenta was adherent and the uterus hourglass, and thus it was impossible to remove it without undue bruising, and it was therefore left. The temperature then fell to normal; but on the afternoon of the 8th it suddenly rose to 102·8°, and I deemed it necessary to complete delivery, which was effected under methylene with considerable difficulty, since the placenta was situated at the summit of the hourglass contraction. It came away in small pieces, till, at a happy moment, the mass was seized and removed. She then be- came convalescent till the 13th, when she complained of pain and fulness over the centre of the right illum, where a tumour of the size of a hen's egg, and quite resonant from before backwards, was felt projecting in the direction of the centre line. It was realised that this was a suppuration of the ragged burst veins, projecting towards the median line, and pushing before it the intestines matted together by the peritonitic adhesions. This rapidly increasing, on the 13th, under methylene, I introduced, as much from the side as possible, a fine trocar, and, getting pus, cut the skin and pushed in a large trocar by the side of the smaller, and through it introduced a drainage tube. The temperature contined normal; but, in spite of drainage tube and syring- ing with a solution of Condy's fluid, the discharge became exceedingly offensive and did not freely escape by the syringing catheter, which entered about three inches; and on Oct. 22nd the temperature rose to 101·8°, and the woman was retrograding. Accordingly then, under methy- lene, I enlarged the opening so as to introduce the finger, and found a mass of rotten grey clots, which were removed by syringing, and a large drainage tube was inserted. From this time she progressed, the temperature remaining quite normal, and is now up walking about, and looking well and fat; yet a probe passes down two inches and a half, but no pus escapes, and there is only a sense of slight deep induration. It is probable that increased strength will heal the channel. She is now at home and will occasionally be seen.

The lessons to be learnt are:—1. Had the operation been performed on September 6th, instead of the 13th, the adhe- sions would have been less vascular, and so no hæmorrhage might have occurred; but what a catastrophe had she had some disease of pregnancy, as dropsy of the amnion, and opinions differed. 2. The lateral clots and the omentum would have been less advanced towards gangrene. 3. The neces- sity of the presence of a foreign body, the drainage tube, might have been avoided. 4. The risk of clotted veins on the proximal side of the pedicle would have been reduced. 5. The exploratory fluid should be taken from the lowest depths of the tumour, or the patient have been previously made to stand or have been placed on the side. The main general axiom derived is, "When in doubt perform an immediate exploratory operation." I trust I may never omit to do this in cases of such diseases with complications, in which, however, the given diagnosis desired for a capital operation is densely clouded. I hope shortly to bring forward a series of cases of ovarian tumour with twisted pedicle, which will show that those in which an immediate opera- tion has been performed have been crowned with complete success, while in those in which delay has occurred fatal results have been courted.

CASE 4. *Uniocular Ovarian Tumour, closely adherent; Ovariotomy; Hæmorrhage; Recovery.*—Mrs. K——, aged twenty-seven, has never been strong, and always subject to great dysmenorrhœa and bearing-down pain, and has worn a pessary. Is said to have had a miscarriage at two months four months ago; since this she has had constant pain in the right iliac region, pain on walking, and much leucor- rhœa. The catamenia is more frequent, and less in dura- tion and quantity.

On Nov. 3rd the abdomen had a hard-feeling tumour, three-fourths to the umbilicus; the vagina contained a large pessary; the os uteri was very high, looked back, was pale, and had a small opening surrounded by slight granulations. No sound passed the inner os. The body of the uterus felt very hard, and on either side of the apparent uterus were firm tumours extending to the sides of the pelvis, only slightly movable. There was no albumen, and the heart and lungs were normal. On Nov. 5th, under methylene, administered by Dr. Gray of South Melbourne, the sound was after some difficulty introduced into an anteflexed uterus two inches

Digitized by Google

and a half. On the introduction of a fine trocar on the 7th, dun-coloured fluid dripped, which was sticky, and under the microscope gave atrophied blood cells and a moderate number of Drysdale's cells. On the 15th Dr. Burke administered methylene at my private hospital, and Dr. Snowball assisted me, when I made an incision two inches and a half long down to the tumour. and aspirated thirty ounces of dirty greyish-brown grumous fluid. The tumour, which was of the right ovary, was completely and closely adherent to the right iliac region and posterior wall of the uterus, and was with difficulty defined and separated. The pedicle was tied with silk. The left ovary was cystic, of the size of a hen's egg, and was similarly tied and removed. There was persistent hæmorrhage from the posterior uterine adhesions, which pressure nearly stopped, but it was deemed necessary to introduce a drainage tube. The operation lasted an hour and a quarter, on account of the adhesions and hæmorrhage. The tube was removed in twenty-four hours, during which there was some escape of bright blood and serum. The temperature was from subnormal to normal for the first week, when a large stool descending raised it to 100°. On the third day there was a tendency to jaundice, relieved by ten grains of subchloride of mercury. The pulse was afterwards 72, and she was convalescing.

I have a strong feeling in favour of private ovariotomies over those in public hospital, having only had one death among the former, which occurred more than four years ago.

(To be concluded.)

THE DISEASE OF INEBRIETY AND ITS TREATMENT.[1]

BY T. D. CROTHERS, M.D.,
SUPERINTENDENT, WALNUT LODGE, HARTFORD, CONN., ETC.

IT is a fact of historic interest that inebriety was called a disease long before insanity was thought to be other than spiritual madness. On an old papyrus found in one of the tombs of Egypt, dating far back into antiquity, was found a clear, explicit recognition of the disease of inebriety. Herodotus wrote, four centuries before the Christian era, that in drunkenness both body and mind are sick. Diodomus, Plutarch, Chrysostom, and Alpian, the Roman purist, all mentioned the disease of inebriety long before and after the Christian era. From that time down to the present century this fact has been mentioned by scientists and philosophers in almost every age. By a strong shifting of events, insanity, which was supposed to be a spiritual affection until a comparatively recent date, is now studied as a physical disorder; while inebriety, which was mentioned as a disease twenty centuries ago, is still invested with the superstition of a spiritual origin. At last, within a quarter of a century, this great truth has been formulated and organised into the realm of practical science. This is a discovery in science, evident from the sharp contradiction which it has provoked, and the same opposition and battle which every new truth must encounter before it is accepted. In the first surveys of a new country only a few general outlines are marked out, leaving wide gaps and stretches to be filled up by other and further studies. In like manner the purpose of this paper is to point out some outline facts of the disease of inebriety and its treatment, and indicate, not only the few facts known, but the wide ranges of the unknown, awaiting future discovery and study.

When inebriety is seen from a scientific point of view, it is found to be controlled by laws, which vary according to certain physiological, psychological, and physical forces, of which heredity, environment, culture, nutrition, brain and nerve vigour, &c., are prominent. When accurately recorded histories of many cases of inebriety are studied and compared, certain fixed ranges of causes appear which seem to follow some regular order of movement. The following is a list of those causes: 1. Certain conditions of heredity, [illegible] physical and psychical shocks, and nerve injuries [illegible] proportion of cases are followed by inebriety. 2. Certain structural changes of the brain and functional irritations precede inebriety in many cases. 3. Certain unstable brain organisations, irregular, retarded, and defective brain developments, manifest in great feebleness or intense activity, are intimately associated as apparent existing causes with many cases of inebriety. 4. Certain diseases seem to have a special predisposition to develop into inebriety with or without any exciting causes. These conditions are uniformly found either alone or combined in all perversions, certain disturbances of nutrition, and nerve cases of inebriety. The outbreak of inebriety varies widely and is gradual and obscure at first, or sudden and precipitous. It may be masked for a long time, or may be very prominent, with long, irregular halts. In the first group of causes the inebriety may be of the dipsomaniac type appearing suddenly. In the second group it is often concealed for a long time; in the third group long halts and apparent recoveries occur. In the fourth group it begins suddenly, and is of short duration. In the second and third groups inebriety is not unfrequently a symptom of insanity and general paralysis, and these diseases follow from inebriety.

The craving for spirits is not the disease, but only the symptom or expression of the disease. It is the demand of the disordered governing centres and general organisation for relief; and alcohol, as a narcotic, supplies this demand most perfectly. Often the first use of alcohol acts like a spark, concentrating and exploding the diseased tendencies which may have been forming or transmitted from the past. Also it may give an impulse or impress to a feeble, unstable organisation, that quickly merges into inebriety. In these cases a train of degeneration is started which will ever seek relief from alcohol. The more impulsive and intense the desire for spirits, the greater the degeneration. When the craving is paroxysmal, with free intervals, the degeneration is central and profound. All these periodical and paroxysmal cases are closely allied to epilepsy. The free intervals may recur with uniform exactness in time and duration. In some cases the return of the drink paroxysm may be predicted with as much certainty as an eclipse of the sun, and the duration of the paroxysm rarely varies more than a few hours. In other cases the paroxysms, both in length and free intervals, are irregular and uncertain, appearing unexpectedly and ending suddenly, in adverse conditions apparently. Thus, in some cases, the inebriate will begin to drink under the most opposed circumstances and surroundings, and will stop suddenly under equally adverse conditions, beyond all rational explanations to account for such acts. In certain cases, the appearance of health and the confident hopefulness of the patient are signs of the approach of a paroxysm. Great mental and muscular activity is often followed by an outbreak of inebriety, lower in degeneration than before. These strange and mysterious phenomena are undoubtedly governed by laws that will be known in the future. Such inebriates, like epileptics, have distinct nerve storms and explosions of morbid energies. This is literally a great, dark continent of the most fascinating psychological interest.

When inebriety is developed, either continuous or periodical, there are distinct traces of a regular order of symptoms. Other diseases may complicate and cover up the order of the march, but sooner or later the same symptoms appear, following the same order. Thus certain brain palsies of the highest centres, certain delusions and hallucinations, certain psychical manias and melancholias, certain morbid impulses and functional perversions, associated with anæmias, hyperæmias, and a great variety of complex symptoms, are sometimes masked with the appearance of health, but generally they are apparent.

A certain number of inebriates, morbidly conscious of their condition, live in the thought of their wickedness and misery; humiliation is coupled with a delirious faith of recovery; they are pleased to serve as examples for others. exalted delusions and delirious manias are always present. Another large class seem thoroughly unconscious of their condition. They have delusions of strength to recover, and believe all accounts of their danger or weakness are exaggerated for the purpose of creating alarm in them. The sense of danger grows less, and their faith in themselves increases in steady progression on to death. Although the action of alcohol may differ widely in different cases, the same general symptoms mark all the stages of acute and chronic degeneration.

Inebriety in America is becoming [illegible]

Digitized by Google

in intentity and maniacal symptoms. The use of alcohol is more precipitate, followed by mental excitement, delirium, nerve and muscle exaltation and depression. Increased culture and intelligence takes away the coarser and more repulsive symptoms of inebriety, but increases the maniacal and suicidal phases and mortality. Inebriety is more concealed to-day than ever before, and more intimately allied with, and terminates more often in, pneumonia, Bright's disease, apoplexy, and various organic and heart affections. Inebriety is increasing, as is shown by the fact of the increased consumption of alcohol in this country and the increased number of persons arrested for inebriety in our large towns and cities. The dipsomaniacs and the intermittent and periodical inebriates are increasing, and the moderate drinkers are diminishing. From a variety of evidence, as yet in outline, it appears that inebriety moves in waves and currents, prevailing like an epidemic, then dying away. This seems to be evident from the statistics of persons arrested for inebriety, and from comparative studies of the numbers of inebriates in different countries. From these data it appears that inebriety steadily increases up to a certain maximum point, then declines to a minimum number, resembling a tide-like movement of continuous ebb and flow. Some of these drink cycles have a period of about eight years. In Sweden it is fourteen years; in other countries it is less. The consumption of spirits in England was found to follow a similar ebb-and-flow movement of eight or ten years. These great movements seem to be beyond any range of causes that will explain their presence. They have been traced in cities and villages of New England in many instances, where it is clearly evident inebriety prevailed at certain times to great excess, then died away, only to reappear again after a lapse of years. The evidence is steadily accumulating, pointing out these great drink cycles, which, like storms, gather and increase up to a certain period, then die away. The great unknown forces and laws which regulate these drink epidemics await discovery. When they are known, then much of the mystery of the strange temperance revivals and agitations; which spring up and sweep over the land, dying away as suddenly as they appear, will be cleared away. Temperance agitations have a strange wave-like movement, evidently controlled by laws unknown. Who will doubt that they may not be the reactions of some high tidal waves of inebriety—the backward swing of some great drink cycle—a psychological protest and consciousness of the presence of some high point of inebriety, which will recede, and with it the agitation will die away. These are but hints, and faint outlines of facts and forces that control inebriety far above the roar of theoretical agitation and personal resolution. Inebriety is a disease governed by certain fixed causes which follow a certain order of events, and the evidence of these and other facts are clearly within the range of a more accurate study and a wider intelligence to remedy and prevent.

In the efforts to check and prevent inebriety, the interest and agitation are increasing far beyond all rational knowledge of the subject. The following are some of the theories on which the present efforts for cure are based. Moralists assume that inebriety is always a vice and sin, the only treatment of which is prayer and conversion. Temperance men and reformers call inebriety the result of a weak will power, and urge the pledge and the force of societies as the only real cure. The temptation of saloons and the facility of procuring spirits are supposed to be active causes, to be broken up only by prohibitory legislation. Ignorance in childhood of alcohol and its effects as a cause is supposed to be remedied by forced instruction in the common schools concerning the nature and character of alcohol. The theory most widely believed is that alcoholic excess is a sin and crime, to be cured by punishment and suffering. It has been stated that in this country during 1886 over 300,000 persons were arrested for inebriety and punished by fine and imprisonment. Yet it is the unanimous testimony of all competent observers that such means for restraining inebriety not only fail, but increase the very disorder they seek to remove. Every individual sent to gaol for inebriety is made more unfit for temperate living, and further removed from health and capacity to recover. He goes to gaol with impaired nutrition and degenerate brain and nerve force. He is suffering from brain anæmia and structural changes, with mental exaltations and depressions. In gaol the quality and quantity of food is ill adapted to restore and build up the weakened organism. The hygienic influences are wanting, the mental influence is bad, and the associates and surroundings still further depress and weaken the mental vigour necessary for restoration. The only compensation for this is the removal of alcohol, which is often a small factor in the treatment. All this and much more can be read in the anæmic faces, tremulous eyes, and depressed movements of inebriates in gaols and prisons. Happily the great delusion of inebriety being a moral disorder, a vice, sin, and crime to be punished, is passing away. In past ages the phenomena of nervous diseases and insanity were regarded as moral disorders, to be remedied by law and Church influence. These remedies, applied most vigorously, made no impression; insanity and nervous diseases steadily increased. To-day history repeats itself in the punishment of inebriates and the efforts of the Church and society to stop drunkenness, while the army of inebriates goes on increasing. As long as the causes are unknown the remedies will fail.

All exact study of the facts indicate that the disease of inebriety is both curable and preventable. We must realise that inebriety is a dangerous disease, not only to society, but to the victims, requiring restriction of personal liberty and legal guardianship, under medical care, in special surroundings. Like victims of contagious diseases, inebriates should be quarantined and forced to come under treatment. Society should not tolerate their presence, or permit them to injure themselves and imperil others by their acts. Dr. Bellaws said long ago: "Inebriates will all eventually be restrained in hospitals and treated medically the moment their liberty becomes dangerous to society." The terms of their confinement will be limited by the conditions and cure of the disorder. Society gains nothing by holding any man prisoner who is fit to be at large; liberty and human rights gain nothing by allowing any man to be at large for a moment who is destroying himself, his family, and his neighbours. Facts and experience show that this can be best accomplished in workhouse hospitals, where restraint and all other appliances can be gathered. These hospitals should be military training asylums, where medical care, restraint, occupation, and general treatment can be applied for long periods. They should be divided into three classes: the first for the chronic incurables, the second for recent cases and the middle classes, and the third for private and wealthier patients. The first and second classes of these military hospitals should be built from the moneys received from the licensed fund, and supported by the same fund and the labour of the inmates. The first class—that for the chronic cases—should be placed in the country on large farms, where various occupations could be profitably carried on. They should be managed by a board, with an expert superintendent, the same as in all State charities. The government should be of military exactness, and every condition of living and surrounding regulated with steady uniformity. Each case should be studied, and a course of treatment pursued that would build up both the mental and physical organisation, providing also rest, change, and occupation in exact surroundings, where every defect is antagonised, and every element of health encouraged and strengthened. The pauper inebriates who are now sent to gaol, and inebriates of all grades should be committed to these hospitals for periods of not less than five years. On apparent recovery within this time, they should be permitted to go out on parole, to be returned at once on relapse. Each one should be employed, and, if possible, be self-supporting. Practically, the final cure of persons in this class might be limited to exceptional cases, but the gain to society and civilisation by housing and treating these poor victims would exceed all computation. The second class of hospitals should be smaller, built in the same way, and conducted on the same plan of exact military care and medical treatment. In the case of persons of limited means who could pay some part of their expenses, and recent cases, who would come voluntarily or by force, under this restraint, for from one to three years' commitments, the same system of parole and occupation should be employed. The third class should be private hospitals, under the same general management and plan. Rest, medical care, change, and occupation should be suited to the needs and demands of all who could command them. They should be built by private enterprise, and be under the general care of the State. Benevolence would endow these places, and the special means of treatment would accumulate rapidly. The great principle of treatment would be, in all these hospitals,

Digitized by Google

to quarantine and house the patient, and treat all the conditions which enter into the disease as well as the disease itself.

These are outlines of the hospitals to be built in the future, the practical success of which is demonstrated in many ways. The inebriate hospitals of to-day are struggling in this direction amid difficulties that would crush out any other work not founded on great principles. The legal power of restraint is limited to months instead of years. Nearly all these hospitals are wanting in location, surroundings, and means of support, except from the income of patients. Means and appliances for occupation and thorough medical care are wanting in many cases. Public sentiment and friends of patients will not sustain the physician in his efforts and methods of treatment. False pride in the friends of patients keeps them away from all hospital treatment, until they are beyond reasonable hope of restoration. Then, as a last resort, they are sent to such places, expecting some extraordinary change. These are only a few of the great difficulties which beset all hospitals for this class, and yet unmistakable evidence indicates a large percentage of positive cures. All authorities agree that over 20 per cent. of all cases treated by the most imperfect means and appliances are cured. The nature and character of inebriety is so largely unknown that its treatment will vary with the hospital and its management. Enthusiasts and non-experts occupy the field in many cases, and try methods of treatment that wider intelligence would condemn. There are three classes of hospitals for inebriates in this country. The first recognises the disease of inebriety, and aims to treat it on thoroughly scientific principles. The second class treats these cases as half disease and half vice, giving prominence to moral means over all physical remedies. The third class are the specific physicians, who adopt special remedies, which are empirical and unfounded on any sound knowledge of such cases. The treatment, like the study of inebriety, is passing through the stage of empiricism; yet, with all the confusion and ignorance which of necessity surrounds these efforts, the actual results far exceed the most reasonable expectation. It may be safely said that no medical field presents more difficulties for the student, as it stretches along the frontier land of sanity and insanity; and no medical field promises grander results in the redemption of the race and requires a higher order of talent than the study and treatment of inebriety. These are some of the teachings of science, which are like head-lights far above the mists and fogs of theory. From these points we shall discover the sources and forces which develop inebriety and indicate the means of cure and prevention. From this standpoint the possibility of restoring the inebriate and stamping out inebriety is only limited by our want of knowledge of the laws and means to accomplish this end. Pausing on the confines of this almost unknown realm of mental disease, and looking over into the darkness of theory and temperance agitation, and empiric efforts to know and cure this disorder, we are assured that here, as elsewhere, the same eternal reign of law and order exists. Here we shall find the same causes and effects, the same circumstances and conditions, which are active in developing the epileptic and the insane, the inebriate and the criminal, all following some unknown lines and obeying some unknown forces as fixed and eternal as that which governs the planets. Along this border line science is gathering its forces, and, like the problem of the stars, its mysteries can only be solved along the line of accurately observed fact.

THE SANITARY REGISTRATION BILL.—At the ordinary meeting of the Council of the Sanitary Assurance Association, 5, Argyll-place, Regent-street, on Monday last, Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair, the following resolution was unanimously passed, on the motion of Mr. H. Rutherford, seconded by Mr. Andrew Stirling:—"That the principle of the Sanitary Registration of Buildings Bill—viz., that the law should forbid any building being used for public or semi-public purposes, unless and until the arrangements for the water supply, drainage, and ventilation of such building shall have been certified as satisfactory by some qualified person—having been very widely approved, a determined effort ought to be made to pass the Bill into law during next session, and in order to facilitate its progress in Parliament it will be desirable to introduce the measure in the House of Lords."

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

A SERIES OF RENAL CASES, WITH REMARKS.

(Under the care of Mr. HULKE.)

THE cases which we publish below are illustrative of renal conditions which come under the care of the surgeon for treatment. The remarks made by Mr. Hulke on each case point out the special points of interest; but we would especially draw attention to Case 4, where the patient recovered from a condition which was at one time regarded as hopeless. The cases are reported by Mr. G. S. Ware, house-surgeon.

CASE 1. *Severe blow in the loin followed by copious and long-continued hæmaturia; scalp wound; concussio cerebri.* A well-grown, muscular labourer was admitted into the Founder ward on Dec. 14th, 1886, suffering from concussion of the brain and scalp wound. In addition to these injuries he had a bruise on the left loin. He was said to have fallen headlong off a scaffold twenty-eight feet above the ground, and to have struck his left side on a projecting beam. The first urine voided contained a very large admixture of blood, and the hæmaturia continued, with slight variations in the quantity of blood, until the 25th of the same month, when an evident decrease was first noted, coincidently with the exhibitions of acetate of lead in doses of three grains every three hours. Visible traces of blood did not, however, finally disappear from the urine until Jan. 3rd, about which date a small quantity of pus was noticed in it, and a few hyaline casts.

Remarks by Mr. HULKE.—It hardly admits of doubt that the source of the hæmorrhage was the kidney, this organ having sustained some degree of laceration, for the amount of blood was too great to have proceeded from the ureter, and there was not anything to suggest a vesicular origin. That such lacerations of the kidney are not necessarily fatal without operative intervention is, it is believed, abundantly established by experience, and they do not necessarily demand nephrectomy; presumably this should be restricted to the severest forms of injury. In this and in other similar cases acetate of lead has appeared to be decidedly useful.

CASE 2. *Hydronephrosis treated by tapping.*—On Jan. 14th, 1885, a maidservant, aged thirty-three, was transferred by Dr. Cayley to Mr. Hulke's charge for the exploration of an abdominal swelling. The left half of her abdomen was occupied by a swelling which reached from the vertebral column forwards to about an inch and a half beyond the middle line in the level of the umbilicus, from which point its anterior border extended downwards to within one inch of the anterior superior spina ilii. The whole area thus defined was dull, and it fluctuated distinctly. A narrow resonant band intervened between it and the hepatic dulness, and the left inguinal region also gave a clear note. A vaginal examination established the separateness of the abdominal swelling from the pelvic organs. The urine was scanty, the total quantity voided on three successive days being 16 oz., 13 oz., and 12 oz.; its specific gravity was 1028; its reaction was slightly alkaline. The woman stated that she had enjoyed fair health, and had never had any serious illness until the present. She had first noticed her abdomen to be swollen only a month previously. She herself had attributed this to "wind." Two doctors had seen her, one saying she had "distension of the bowels," the other that she had dropsy. The cyst was emptied by aspiration through the loin, 22 oz. of fluid being drawn off. Its colour was greenish yellow; its specific gravity 1022; its reaction slightly alkaline; boiled with nitric acid it gave a copious precipitate of albumen. The only formed elements noticed in it were a few squamous epithelial cells, some leucocytes, and red blood-corpuscles. It was quite devoid of urinous odour. After the operation she expressed herself as being much relieved,

Digitized by Google

and on Feb. 2nd she returned to the medical ward, from which she was discharged convalescent on April 20th.

Remarks by Mr. HULKE.—Its situation, unchanged by posture, the entire absence of resonance posteriorly, its proved independence of the other solid abdominal viscera and of the pelvic organs, collectively afford a very high degree of probability that the swelling was a renal cyst. The character of the fluid drawn off does not negative this supposition, since in advanced stages of hydronephrosis the fluid is certainly in some instances distinctly albuminous and wanting in urinous smell, and the date of origin after cystiform dilatation of the kidney may have long preceded the time of discovery of the swelling. The result, even if it should not prove permanently good, justifies the propriety of the treatment by aspiration.

CASE 3. *Renal calculus; pyonephrosis; lumbar incision; subsequent extraction of the stone.*—On Jan. 27th a charwoman, aged forty-six years, who had been admitted into the hospital under Dr. Cayley, was transferred to Bird ward for operative treatment. At that date the right half of the abdomen was occupied by a swelling, which extended forwards from the vertebral column to slightly beyond the middle line, and reached downwards from the hypochondrium nearly to the groin. This entire area was dull, and throughout it fluctuation was distinct. Between its upper edge and the liver, and also between its lower limit and the pelvic brim, was a narrow resonant interspace. The reaction, the specific gravity, and the average daily quantity of urine were normal. The patient stated that twenty years previously she had first had an attack of pain in the right loin, accompanied by vomiting; and at that time she was told that she had a stone in the kidney. From that date she had seldom been long without lumbar pain. Ten years ago, during such an attack, she first noticed a swelling in the loin. She was not aware whether at any time her urine had contained pus or blood. Her present symptoms, together with her history, were considered to indicate a cystic dilatation of the kidney, presumably due to calculous obstruction, but they did not appear sufficient for the differentiation between hydro- and pyo-nephrosis. The absence of pyrexia favoured the former supposition. On the 28th of January a renal cyst was opened by lumbar incision, giving escape to a very large quantity of a thin, slightly opalescent fluid, after which the edges of the opening in the cyst were easily brought to the surface of the external wound and stitched to the skin. Neither with the finger passed into the cyst nor with a long probe could a calculus be detected, but the cavity was so large that its exploration was necessarily very incomplete. With the exception of a transitory rise of temperature to 101·6° F. on Feb. 1st—coincident with the occurrence of a slight blush of redness of the integument between the wound and the crista ilii, which soon disappeared — the temperature remained normal. A few days later a slight cystitis and also diarrhœa supervened; these also quickly passed off. On March 31st, the external wound having closed except at the exit for the drainage tube, a calculus was felt with a probe, lying not far from the surface. Two days later this was easily extracted. It broke into several pieces, and by an oversight these were unfortunately thrown away before they had been carefully examined in respect of their constitution, and before they were weighed; their aggregate bulk probably equalled that of a pigeon's egg. After this the patient made rapid progress, she was soon allowed to leave her bed, and she was shortly afterwards sent into the country to a convalescent home. On her return to the hospital to report herself, in the early summer, her condition and appearance were so improved that at first she was not recognised. A small indiarubber apparatus efficiently protected her dress from a scanty escape of urinous fluid from a fistula in the scar. She found her condition so tolerable that she would not entertain any idea of further operative procedure.

Remarks by Mr. HULKE.—In the feeble condition in which the patient was on Jan. 28th it may well be doubted whether she would have survived the shock and the later risks incidental to removal of the immense renal cyst by abdominal section, and the selection of treatment by lumbar incision and drainage may claim to have been justified by the result. The large size of the calculus, and the ease with which it was felt and seized when by the contraction of the cyst it had been brought towards the external wound, favour the supposition that it had been impacted in the pelvis of the kidney, and had not passed into the ureter. The most important lesson deducible from a review of the whole history of the case is the propriety of recourse to operative procedure directly the diagnosis is established and before the structural integrity of the kidney is seriously impaired. Had this been done in the present case, many years of suffering and broken health would have been averted. It has been abundantly established by experience that exploration of the kidney through a lumbar incision for the detection of a calculus, unless attended with inordinate roughness of manipulation, entails relatively small risk, and that the danger of a judiciously performed nephro-lithotomy is not very much greater, whilst the gain from a successful extraction of a calculus can scarcely be over-estimated.

CASE 4. *Pyonephrosis; consecutive post-renal abscess; extreme irritability of urinary bladder; lumbar incision for drainage of abscess and renal cyst; later exploration of urinary bladder by external urethrotomy.*—S. G——, an extremely emaciated, pale, very feeble youth, aged about fifteen years, whose whole aspect bore witness to long and severe suffering, was admitted into the Founder ward on Feb. 12th, 1884. At that date the right half of his abdomen from the vertebral column behind to the middle line in front, was occupied by a swelling, which throughout its whole extent fluctuated and was dull on percussion. Its anterior border descended almost vertically from the ensiform cartilage to the umbilicus, from which it extended obliquely towards the anterior superior crista ilii. No resonant interval occurred between this swelling and the area of hepatic dulness. In the right line was an evident unnatural fulness, and there fluctuation was very distinct. The patient complained but little of his loin and abdomen, and referred his sufferings, which were very great, chiefly to the glans penis. His urinary bladder was very irritable, expelling its contents with straining at short intervals, seldom exceeding ten minutes. Examination of the bladder with a sound, and exploration of its base with the finger through the rectum, yielded a negative result. The urine had a slightly acid reaction; its specific gravity was 1020; it contained a trace of pus and albumen. The boy said that his illness had begun, about three years previously, with severe pain in the right loin, darting thence down the thigh, and that after this blood and matter had been noticed in his urine. A very large quantity of pus was evacuated by a lumbar incision, opening, as was thought, the cystically dilated suppurating kidney. Neither with the finger nor sound could a calculus be detected. A large drainage tube was inserted. This was followed by marked relief, and his general condition manifestly improved; but later, in the first week in April, the penile pain returned, and the irritability of the urinary bladder greatly increased. The incision, which had contracted around the exit for the drainage tube was extended, and the cavity again explored. It then first became apparent that the space directly drained by the tube was not the dilated kidney, but that of a very extensive post-renal abscess communicating with a still larger renal cyst through a small opening in the back of the kidney. Through this opening, when dilated, the finger entered a renal cyst too large to allow its extreme limits to be fully traced. No calculus could be discovered. The escape of many ounces of pus proved the previous drainage to have been imperfect. A large drainage tube was passed into the kidney. The relief following this better drainage was very distinct; but again, a few weeks later, very great penile pain returned, and with this the recurrence of excessive irritability of the urinary bladder, the uncontrollable urgency to micturate at intervals of only a few minutes, was quickly exhausting his little remaining strength. On June 25th the interior of the urinary bladder was explored with the finger through an external urethrotomy, but nothing abnormal was detected unless it were two little hard knots in or under the mucosa of the anterior wall, which it was conjectured might be miliary tubercles. An attempt to sound the lower end of the ureter through its vesical orifice was unsuccessful. Nothing abnormal was discoverable by the finger in this situation, and no calculus could be felt with a long probe passed from the loin downward in the direction of the ureter until it nearly approached the finger in the bladder. A large drainage tube was placed in the renal cyst, and another in the bladder through the perineal incision. Again some relief was obtained. The penile pain and vesical irritability lessened; his appetite improved; he regained strength, so that on August 1st he was able to leave his bed, and a few

Digitized by Google

days later was taken into the garden. After this his condition quickly improved, and on August 20th he returned home. At that time the discharge from the loin was slight; a minute fistula remained in the perineum, through which occasionally a few drops of urine escaped; and the irritability of the bladder had greatly abated. In the following November he re-entered the hospital in a condition of extreme weakness, having then obstinate diarrhœa, marked enlargement of the liver and spleen of an amyloid character, and highly albuminous urine. The lumbar opening discharged daily about one ounce of pus devoid of urinary smell. In this condition further operative procedure appeared only likely to hasten the end, and in February, 1885, realising that his recovery was not expected, he expressed the desire to return to his home, which was acceded to. Contrary to expectation, he did not die, but came two or three times in the course of 1886 to see the ward sister (who had been most kind and attentive to him), and each time he appeared to be in better health. On June 3rd, 1887, he was seen and examined by Mr. Hulke's house-surgeon, who made the following note of his condition at that date:—"The boy presented himself on June 3rd, and was found to be in apparently good health. He stated that he passed urine regularly. There was a small sinus in the right loin. He said that at intervals his loin swelled there and discharged."

Remarks by Mr. HULKE.—The impaction of a renal calculus obstructing the pelvis of the kidney or ureter, cystiform dilatation of the organ, pyonephrosis, and latterly the formation of a large abscess behind the kidney, comprise the chain of circumstances suggested by the history of the patient's illness and by the symptoms present at the date of the lad's first entry into the hospital. Upon a review of the whole case as now recorded, the question forces itself upon the reader's consideration whether, in the first instance or subsequently, instead of the more limited procedure of lumbar incision and drainage, it would not have been better practice to have combined with this measure the extirpation of the cystiformly dilated suppurating kidney by an abdominal section. It was obvious that such extirpation, if practicable, could only have been performed by abdominal section in the presence of the circumstances already existing when the lad first entered the hospital. In view of the unavoidable purulent contamination of the peritoneal cavity and the great shock inseparable from so extensive and severe an operation, the procedure adopted seemed at the time the only prudent course. The non-detection of a calculus may not be taken as implying that such had never been present, causing the obstruction which, it is assumed, led to the cystiform dilatation of the kidney, because the cyst was so very large that a stone enclosed in it might easily have eluded discovery by the finger and sound, or it might have escaped from the kidney when the large post-renal abscess formed, and been lost in this. It must be allowed that there was no absolute certainty that the probe passed from the loin towards the urinary bladder actually traversed the ureter, although the ease with which it took the course of this tube favoured the supposition that it did so. When seen by the house surgeon in June last the youth's condition had so improved, it had become so tolerable, that he would not allow any examination of the sinus in the loin with a probe, nor would he consider the probability of further operative measures.

CITY OF LONDON INFIRMARY.

RETENTION OF URINE PRECEDING APOPLECTIC ATTACKS.

(Under the care of Mr. W. GEM.)

THE following cases illustrate the above heading.

W. S——, aged sixty, labourer, of temperate habits. Has had rheumatic gout for some years. Was admitted into the Infirmary in 1882, and has been readmitted off and on ever since for rheumatic gout. Heart sounds normal, but has atheromatous arteries. Has had iritis, but no other defect of vision. Urine normal. Suffered from retention for six days, after which he had a severe apoplectic attack, with consequent left hemiplegia.

G. [illegible]——, aged forty, carman. Intemperate. Had rheumatic [illegible] time. Was admitted in 1882, and has been [illegible] and on ever since for rheumatism and cardiac [illegible]. His albumen in urine, but sight is good. Had [illegible] for seven days, followed by an apoplectic attack [illegible] right hemiplegia.

W. C——, aged fifty-seven, labourer. Intemperate. Had rheumatic gout for some years. Admitted for such in 1885. Heart sounds normal. Double optic neuritis, but urine normal. Had retention for ten days, after which he had a severe apoplectic attack and complete left hemiplegia.

G. W——, aged forty-nine, baker. Habits not known. Admitted for melancholia, and was transferred to an asylum. Being discharged some time after on trial, he was readmitted for subacute rheumatism. Heart sounds normal. Sight not ascertained (too restless). Urine normal. Had retention for four days, and then had an apoplectic attack, with subsequent right hemiplegia.

All the above cases were treated as follows:—Perfect rest, blistering the nape of the neck, croton oil, and warmth to feet, *plus* the following drugs—bromide of potassium, decoction of aloes, and compound spirits of ammonia; followed up afterwards with the iodides. The very best results were obtained by this treatment, with the exception of the last case, which is recent.

Remarks by Mr. GEM.—It is with reticence I bring forward the above cases, as such may have been discussed in the ephemeral literature of the day. The drugs above mentioned need no comment from me, as their actions are too evident, but I may say that I have had the most favourable consequences from them in two cases I anticipated, where retention had been complete for two or three days. The query of course arises, Would such cases have gone on to an apoplectic attack? I have every reason to suspect such an unfortunate accident, as the one patient had an intense localised headache, with retinal hæmorrhages; the other not so well marked. The first one was readmitted after some time with a recent hemiplegia, showing that such an untoward event had been previously warded off.

PATHOLOGICAL SOCIETY OF LONDON.

Compound Comminuted Fracture of Lower Jaw, with Rupture of Nerve.—Central Fibro-sarcoma of Tibia.—Congenital Inguinal Hernia.—Cyst of Cerebellum and Adrenal Body.—Lardaceous Disease in Congenital Syphilis.—Congenital Hydronephrosis.—Adenoma of Mamma, with supervention of Scirrhus.—Separation of Upper Epiphysis of Radius.—Fracture of Lower Epiphysis of Femur, with Bony Union.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart. President, in the chair.

Mr. GODLEE read the report, signed by Dr. Norman Moore and Mr. Clutton, on Dr. Jacob's specimen of Tumour of the Skull. They found genuine myxomatous tissue, but nothing sarcomatous; the diploë was the seat of origin of the growth; and the report therefore accepted Dr. Jacob's opinion that the tumour was a myxoma.

Mr. SPENCER showed a specimen of Compound Comminuted Fracture of the Lower Jaw, in which the inferior dental nerve was torn; the latter accident was rare. In this case direct violence caused the fracture in a woman aged fifty; it was vertical fracture; there was extreme pain for some time, and anæsthesia of the chin and parts supplied by this nerve. There was no displacement of the fragments, and no bleeding from the inferior dental artery. In reply to Sir James Paget, Mr. Spencer said that the necrosed portions came away during the healing; and in reply to Mr. Godlee, he said he could not say whether the teeth were anæsthetic or not.

Mr. FREDERICK EVE showed the Macerated Bone for a Central Fibro-sarcoma from the Tibia, with extreme Cystic Degeneration. There was much cholesterine in the fluid contents. The solid part was partly fibrous, partly sarcomatous, and partly had undergone mucoid degeneration. It came from a man aged twenty-four; the tibia had been fractured ten years before, and the tumour grew at this site. He had never seen so much fibroid conversion of a sarcoma before, except in those developed in the jaw; the extreme cystic degeneration was also rare. The specimen reminded him of that shown by Mr. Bilton Pollard two years ago, in which case the Morbid Growths Committee could not decide the inflammatory or sarcomatous nature of the tumour of the tibia.

Digitized by Google

PAGET remarked on the long period of time that elapsed between the traumatism and the tumour.—Mr. BOWLBY related a case of a child aged three, in whose tibia there was a central sarcoma expanding the bone. From the centre of this some fluid was removed from a large cavity in the upper third of the tibia. After the operation of removal of the fluid the child gradually improved and the bone healed up. He asked for information as to the laying open of such cases.—Sir JAMES PAGET referred to his paper on the Enucleation of Tumours from Bone, and in this there were, he believed, cases of large cysts containing blood, which were emptied and did well. In one case of Mr. Thomas Smith's in which laying open was practised the case did well, and the child remained well, and was, indeed, still living.

Mr. BLAND SUTTON exhibited and made some remarks on two specimens of Congenital Inguinal Herniæ in Monkeys. He stated that, with the exception of the gorilla and some chimpanzees, man is the only mammal in which the funicular process of the peritoneum becomes normally obliterated above the testis. If, as some surgeons maintain, a patent funicular pouch predisposes to hernia, it should be very frequent in monkeys. This, however, is not the case, for out of more than 800 monkeys he had examined post mortem, only three presented herniæ—two were congenital epiploceles, the third an entero-epiplocele. Reference was made to a large inguinal hernia from a monkey preserved in the College of Surgeons, a Hunterian preparation, in which the omentum and colon occupied the sac. A re-examination of the specimen showed that the testis had a proper tunica vaginalis. Further, the sac also contained several large hydatid cysts. As a curiosity, a drawing of a hernia in a frog was shown.—Mr. JONATHAN HUTCHINSON, jun., had never observed inguinal hernia in monkeys, though he had frequently demonstrated the patency of the funicular process. He did not think that the observation could be taken to militate against the theory that the patent funicular process was a factor in the production of inguinal hernia in man, but it tended to prove that a long mesentery could not be the efficient cause. In monkeys the mesentery was always long, and could be pulled down below the scrotum; yet inguinal hernia was, as Mr. Sutton said, extremely rare.

Dr. CHARLEWOOD TURNER showed a specimen of Cystic Tumour in the cerebellum and right adrenal from a man aged forty-four, who had served as a policeman ten years, and got a good deal of knocking about. Eight years before his death he received a blow on the forehead from a brick. His symptoms commenced with headache referred to the occiput and forehead eighteen months before his admission to the hospital, with failure of sight and deafness of the right ear, and vomiting. He subsequently had incoördination of movements, with a tendency to fall to the right side. He became dull and torpid, and died in coma. There was a tumour at the right border of the cerebellum, and another on the upper surface, contiguous to the anterior part of the middle lobe, which it had compressed. The centre of each tumour was occupied by a cyst. The growth consisted of a fine reticulum, with round and elongated nuclei, traversed by a network of vessels, some of which presented varicose dilatation occupying much of the field. The right adrenal was converted into a tumour of the size of a fist, which consisted of a large cyst surrounded by a wall of growth, having an adenoid structure resembling that in the cerebellar tumour, but more fibrous. There was a cyst in the liver containing clear fluid and cholesterine, and there were several cysts in the left kidney. This wide-spread cystic disease was interesting, and in a case recorded by Dr. Pye-Smith in vol. xxxvi. of the Transactions there was a simple cyst in the cerebellum, associated with small cysts in the pancreas and kidneys.—Dr. HALE WHITE said it would be interesting to know whether the patient was insane, because in some of the insane general cystic degeneration was found, as had been communicated to the Society by himself and Dr. Savage in their paper on Holes in the Brain.—Mr. STEPHEN PAGET said that he had found that the suprarenals were involved with secondary growths in cases of cancer, and these organs were symmetrically affected, and yet when they were involved the kidneys escaped. He asked which was the primary disease in Dr. Turner's case.

Dr. HALE WHITE showed specimens of Congenital Syphilis causing lardaceous disease of the viscera, gummata, and fibrosis of the liver, and chronic peritonitis. The patient was a girl aged seven years, both of whose parents had syphilis, and who herself presented most of the signs of congenital syphilis. The liver could be felt with a hard rounded edge just above the iliac crest; the spleen reached below the umbilicus; there was some pain and tenderness in the abdomen; the left eye showed disseminated choroiditis and optic neuritis; the glands in the right axilla were enlarged, and there was a painful node over the head of the tibia; the urine was albuminous, and this decided the diagnosis in favour of lardaceous disease. She improved under treatment, but ultimately succumbed to an attack of acute tonsillitis. The liver weighed 61 oz.; it was hard, rounded, with radiating fibrous depressions all over it; there was also some cirrhosis; at the anterior part there was a gumma the size of a walnut; it was extremely lardaceous throughout, as was also the spleen, which weighed 16 oz. The kidneys weighed 12½ oz., and showed both tubal nephritis and lardaceous disease. The small intestine and cervical glands were slightly lardaceous; there were several bands of fibrous tissue indicative of old peritonitis. There was no sign of there ever having been any suppuration. The lardaceous deposit was seen very well under the microscope. This case showed three very rare manifestations of congenital syphilis: First, lardaceous disease; second, chronic peritonitis; third, fibrous scars and gummata in the liver, in addition to cirrhosis.—Dr. ANGEL MONEY said that lardaceous disease in children dying of congenital syphilis was undoubtedly uncommon; but probably lardaceous degeneration was not so rare an occurrence as might be supposed from this, for the reason that children seldom died at so advanced an age as seven years, unless from other diseases. In children under two years, when deaths were frequent, he had never observed lardaceous disease.—Dr. COUPLAND said, so far as he knew, no case had been recorded in which only congenital syphilis was operative in the causation of the lardaceous disease.—Dr. HALE WHITE thought it was rare, even clinically, for signs of visceral enlargement were uncommon and albuminuria wanting.

Dr. DAWSON WILLIAMS showed a specimen of Dilatation of the Ureters and of the Pelves of the Kidneys observed in a boy aged five and a half years. There was no history of calculus nor of any illness beyond diarrhœa until about six months before death, when a swelling, subsequently identified as the distended bladder, was first noticed. For two or three months earlier he had had incontinence. Six weeks before death he had two attacks of convulsions, probably uræmic, with partial unconsciousness. When he came under treatment at the East London Hospital for Children (Shadwell) there was slight irregular fever, the bladder was found to be habitually distended, a small quantity of urine being passed every few minutes; on one occasion Mr. Parker drew off one pint, and no urine was passed for twenty-four hours, when the bladder was again full. The urine was persistently albuminous; at a later stage much blood was passed with the urine; subsequently this was replaced by pus. Death was due to suppurative nephritis, which was found to be more advanced in the right kidney. Both organs were much enlarged, the superficial measurements considerably exceeding the average in the adult; the enlargement appeared to be due to dilatation of the calyces; the pyramids projected into the calyces, and extended quite to the surface; the cortical substance occupied the intervals between the pyramids. The collecting tubes were enlarged. The ureters were much dilated, and had the general external appearance of a coil of the ileum. The bladder was much trabeculated, and there were numerous hæmorrhages into the mucous membrane. There was no obstruction post mortem to the flow of urine from the kidney to the bladder, and pressure on the bladder caused regurgitation into the ureters and pelves. A catheter was easily passed during life, and there was no reason to suspect any obstruction. The dilatation and trabeculation of the bladder and the presence of fibrotic changes in one kidney were mentioned as facts which might be quoted in support of the theory that the dilatation had been produced by past obstruction, but for two reasons it was suggested that the case was an example of congenital dilatation of the ureters and pelves (so-called congenital hydronephrosis); in the first place there was a complete absence, both from the history and the post-mortem appearances, of any cause for the dilatation; and, secondly, the anatomical characters of the abnormal parts, which included an unusual size of the collecting tubes, seemed to favour the theory of an error of development, because the ureters, pelves, and collecting tubes were developed from the same mass of blastema, the collecting tubes growing out from the ureter into the metanephric blastema.—Mr. GODLEE thought such cases were

Digitized by Google

most puzzling to explain; chronic catarrh or stone could not have been the cause, for the bladder was greatly hypertrophied.—Dr. HALE WHITE referred to a card specimen shown at the last session.—Mr. BLAND SUTTON agreed with the view that it was a case of congenital hydronephrosis.—Dr. ANGEL MONEY concurred in the view, and mentioned a case of lipæmia in which there was congenital hydronephrosis on the left side, and a fibrous atrophied kidney on the right side. There was doubtless an intra-uterine want of vitality, which led to various errors of development in different directions.—Dr. DAWSON WILLIAMS, in reply, remarked that the two kidneys in his case were different, one being more fibrous than the other.

Mr. JONATHAN HUTCHINSON, jun., after quoting Sir James Paget's statement that cancerous disease had never been observed to occur in adenomata of the breast, said that the patient's mother had an adenoma of the breast at the age of fifty-four. The daughter had noticed a tumour of the breast for many years, but it began to grow at the age of forty-four. The original tumour was an adenoma, while round it was a scirrhous growth of the round-celled variety, which in parts infiltrated the adenoma; but it could not be determined whether the scirrhous growth started in the adenoma or not.—Mr. EVE had described a similar specimen from St. Bartholomew's museum. The growth was a scirrhus except in the centre, where it included a nodule of adenoma.—The PRESIDENT said he had never met with a case in which adenoma had disappeared; he thought it very proper to advise their removal, as he had seen several develop into recurrent fibro-cystic tumours.

Mr. MANSELL-MOULLIN showed a specimen of Separation of the Upper Epiphysis of the Radius. The injury that caused it had greatly torn the forearm of a boy aged sixteen. The solution of continuity took place between the cartilage of the epiphysis and the bone of the shaft. The orbicular ligament was much torn. He also showed a specimen of vertical Fracture through the Lower Epiphysis of the Femur, which had united by bone, also from a boy aged sixteen, who had sustained one year previously a compound fracture into the knee joint; afterwards a swelling formed in the popliteal space, which became quite full, and there was distinct pulsation, which led to the diagnosis of arterial hæmatoma. Suppuration into the knee joint led to amputation through the lower end of the femur, when it was found that the fracture had united obliquely, and that a fragment had caused ulceration of the popliteal artery, hence the hæmatoma. The popliteal vessel was ligatured in two places, but this was followed by suppuration into the knee joint. After maceration the lower epiphysis separated at the epiphysial line.

CLINICAL SOCIETY OF LONDON.

Suprapubic Drainage of the Bladder for Enlarged Prostate.—Prostatectomy by the Suprapubic Incision.

AN ordinary meeting of this Society was held on the 11th inst., Dr. W. H. Broadbent, F.R.C.P., President, in the chair. A most interesting evening was spent in the discussion of the Surgical Treatment of Enlarged Prostate.

Sir HENRY THOMPSON read a case of Enormous Prostate; vesical calculi, free and encysted; urine passed for years by catheter, but now by suprapubic tube, without any catheter, for a year and a half; patient in excellent health. The following is an abstract:—"A gentleman, aged sixty-four, applied to me on April 21st, 1885. All urine was passed by catheter, used sixteen times in twenty-four hours; there being symptoms of stone, verified by sounding, I advised lithotrity.—April 24th: Under ether I unexpectedly found stricture of urethra, which was forcibly dilated by conical metal instruments from No. 8 up to 13 to admit lithotrites &c., enabling me to remove a phosphatic calculus, weighing 142 gr., at one sitting. He soon improved, and used the catheter now only eight times daily. In the autumn severe symptoms reappeared, and he came again. Finding no adequate cause, after consultation with Dr. George Johnson, I decided to perform digital exploration of the bladder through the perineum, and did so on Nov. 4th. The prostate was so large I could barely reach the neck of the bladder with my finger, still sufficiently so to discover there a collection of calculi, evidently movable in a sac. Opening this with the scalpel, I removed six, each with facets, the effects of packing (exhibited). Nothing had been left in the bladder from the previous operation. At the same time the stricture, which had rendered his daily catheterism troublesome, was now freely divided by the knife. He made a good recovery, but the relief was not great. He soon began to pass much phosphatic grit, and suffered greatly, taking morphia largely in consequence; and before the early spring of 1886, having spent that winter in a warmer climate, he required hypodermic injection daily, while catheterism was required more frequently than ever. I advised the suprapubic section and the placing of a tube permanently there as the only chance of saving him, and, if it answered, of rendering his existence comfortable. His friends advised him to decline my proposal for the present, but in the end of April he came to me, regarding life as unendurable, and begged me to do whatever I thought best.—April 29th: Dr. G. Rice Ord, of Clapham, and others present, I performed the high operation, finding the prostate enormously large, and interior of bladder coated with an adhering fibrinous layer containing much phosphatic deposit. I peeled off the layer with some trouble, leaving the bladder quite free from adhering matter. A tube was placed in the wound by which all the urine issued, and he rapidly improved from the cessation of catheterism and pain. In three or four weeks, when he had thus regained health and strength, I adapted a silver plate to the suprapubic region with an opening, admitting a silk gum tube, No. 20 English scale, and consequently very large, one end being in the bladder, the other projecting half an inch from the outer surface of the plate, and attached thereto an ordinary urinal worn in the usual manner. After a few experiments and adjustments, this answered perfectly, and all the attention necessary now was its removal and cleansing once a day, and washing out the bladder, all which he learned to do. He soon left for Brighton, discontinued all opiates, went abroad for the winter of 1886-87, and wrote me last spring that he is 'able to walk two miles, and to be out an hour at a time; the urine good in colour and clear, passing through the tube at night, and not interfering with sleep.' He has not used the catheter since. He called on me soon after, looking the picture of health, cheerful and happy. A few months later he wrote me that the wound had contracted somewhat, and that he had hurt himself by forcibly attempting to push in the tube, and partially lost the route. I advised him to come up at once, and he did so. Giving him ether, I enlarged the wound a little and re-established the channel, and he left me in a few days, the old system being re-established with the same freedom as heretofore, having never at any time resumed the use of the catheter. This was in June last, and I have seen him only once since, about a week ago, in the end of October, and found him as well as ever; active, healthy, and free from pain; in every way far more comfortable than during any part of his long experience of passing urine by the catheter. I employed the suprapubic puncture first in 1869, in University College Hospital, in order to give relief to an extreme case of constantly recurring catheterism, by inserting a tube to give issue to the urine as a permanent channel, which afforded much relief; and I repeated the proceeding with more or less success in five. But a free suprapubic section, inasmuch as it enables the surgeon to detach all chronic fibrinous and phosphatic deposits which are in no other way removable, appears to me a far better method, and I propose it now for adoption in some of those exceptionally formidable developments of the prostate and associated disease of the bladder which sometimes occur, as the only chance of prolonging life and obtaining relief from terrible sufferings. Of this proposal the case reported is a remarkable illustration, while it is perhaps almost unique from the complication of morbid conditions present in one patient."

Mr. M'GILL read a paper on Suprapubic Prostatectomy, and related three cases where the operation had been successfully performed. The operation consists in opening the bladder above the pubes in the usual manner, and removing with scissors and forceps that portion of an enlarged prostate which prevents the outflow of urine. Case 1 had suffered from urinary symptoms for seven years, and had not been able to pass urine without a catheter for seven months. Six calculi, weighing 174 grains, and a portion of the prostate as large as a walnut, were removed by suprapubic incision. The patient made a speedy recovery, and did not require to use a cathether. Case 2: Symptoms of prostatic enlargement for two years, acute symptoms for a fortnight, fetid urine, and frequent micturition. The patient was treated for three weeks by ordinary methods without

Digitized by Google

benefit. The middle lobe of the prostate, the size of a bean, was removed with immediate benefit. He left the hospital on the twenty-seventh day with the wound healed, and passing urine without difficulty. Case 3: Prostatic symptoms for six years. Acute symptoms of greater and less severity for three years. On admission into hospital the patient was found to be extremely ill. He vomited all his food, had constant diarrhœa, and passed putrid urine, which deposited one-third of its bulk of pus. On opening the bladder the ureters were felt to be much dilated. The projecting portion, the enlarged prostate, was removed. He made a quick and satisfactory recovery, and was able to micturate without difficulty. The benefits derived from the operation are of two kinds: first, acute symptoms are relieved by the drainage of the bladder; and second, the cause of these symptoms is removed by excision of a portion of the enlarged prostate. As yet the operation has only been practised in acute and urgent cases; it is not improbable that in the future it may be resorted to before any acute symptoms intervene.

Mr. CHRISTOPHER HEATH spoke of the great advantage of the suprapubic drainage in cases of long-standing prostatic enlargement with its consequences. He considered Mr. M'Gill's action as a new departure. Some years ago Sir William Ferguson tried the removal of enlargements of the prostate by the perineal incision as in lithotomy, but the hopes raised by this method did not appear to have been fulfilled. Mr. M'Gill's mode of treatment may be said to have opened up a great field for enterprising surgery. Mr. Heath remarked that few surgeons were familiar with the aspect of a prostate as seen from within the bladder in the natural state. He congratulated Mr. M'Gill on his success.—Mr. BARWELL raised the question whether it was safe to make wounds in the prostate and bladder whilst the urine was in a fetid condition.—Mr. HENRY MORRIS considered that theory and experience might show that the suprapubic method of removing the prostatic overgrowth might not perhaps be the best method of procedure. Sir William Ferguson and Mr. Bryant had removed portions of enlarged prostate by the perineal lithotomy section in cases of vesical calculus. The operation of removing the prostatic overgrowth through the perineum without the bladder being incised was discussed, and it appeared in a favourable light; the upper part and sides of the prostate were not to be removed, but the posterior part between the bladder and rectum; and Mr. Morris asked whether we ought not to attempt to shell out the posterior part of the prostate through the perineum, the one finger being placed in the bladder through a median urethrotomy incision; he thought by this method we might record successes without the necessity of any suprapubic operation. He referred to a case of suppuration in and around the prostate, which he attempted to heal by median urethrotomy and drainage, but without success; extensive fistulous channels formed in the perineum, and to remove irritation and promote the healing of these parts Mr. Morris performed the suprapubic operation for draining the bladder. At the operation, the fistula, which led from the bladder into the perineum, was distinctly visible on inspection through the high incision. The greater part of the perineal wound closed, but the man left Middlesex Hospital when that institution closed for summer cleaning, and Mr. Morris had not heard the termination of the case. The instrument he employed for draining the bladder through the suprapubic opening somewhat resembled that of Sir Henry Thompson's, but had the additional advantage of a ball-and-socket joint. Mr. Morris considered that in the method of suprapubic drainage we held a means for relieving cases of perineal fistulæ.—Mr. QUARRY SILCOCK supplied the previous history and sequel to Mr. Morris's case. When he first saw the man there appeared, to be an ischio-rectal abscess, which was opened and was followed by the development of much granulation tissue. After Mr. Morris had drained the bladder by the suprapubic opening, still some urine trickled away from the perineal fistula, which refused to heal despite every attention. The patient was now in a workhouse adjoining St. Mary's Hospital, and there was practically no improvement in his condition.—Mr. T. BRYANT considered the suprapubic drainage to be now proved to be of great value, and such success as has been found by its use must tend to diminish the fear of practising it. He confessed to a long liking to, and personal preference for, draining through the rectum; but he was satisfied that the bladder could be well drained above the pubes. Sir Henry's case could, indeed, only have been treated in that way, and there could be no question as to its value. Mr. M'Gill had introduced a new subject of an interesting and pleasing nature. He was not disposed to criticise so frank a paper as Mr. M'Gill's. The first case appeared to be that of a rather young man, and some doubt might be entertained as to whether a large prostate really existed. It must remain an open question as to how far the suprapubic method of prostatectomy was likely to be better than the perineal. He himself inclined to think the perineal was the best, but this must be a subject for experience. He had on two occasions removed enlarged lobes of the prostate; both were cases of lithotomy. The first tumour was removed unwittingly with the stone. The patient was alive and well seven years after the operation. In the second case, the tumour was designedly removed from the posterior part of the prostate after the removal of the stone. Eighteen months later the man was in good health. He inquired how long the first two cases (of Mr. M'Gill) could retain the water.—Mr. H. BENNETT discussed the best method of approaching the prostate with a view to its removal, and he thought the suprapubic method had advantages. He related the case of an old man aged seventy, who was admitted into St. George's Hospital, under the care of Mr. Holmes, for acute retention resulting from old prostatic disease. An incision was made through the centre of the perineum; the finger could not be passed into the bladder; the catheter was passed and the bladder drained thereby, but, nevertheless, much distress was occasioned, and the patient but little, if at all, relieved from pain. He returned later to the hospital, after having gone out and begged to have something done to relieve his distress. A suprapubic opening was made; a stone not previously detected was found and removed; many portions of the large prostate were deliberately cut away—enough to fill the palm of the hand. This procedure relieved the patient from all pain and distress, but death followed in three weeks from exhaustion, the old wound not having healed. The termination might have been different if the patient had had the suprapubic operation performed before his kidneys and general system had become so deteriorated.—Mr. BOWLBY related a case which had been under the care of Mr. Willett at St. Bartholomew's Hospital. It was a case of vesical stone removed by perineal lithotomy; a large prostate was found, and this tumour was enucleated through the perineal incision; there was no pedunculated portion, but the sessile tumour was freely removed by the aid of scissors and finger; the parts removed equalled half an orange in size. The patient was much benefited; passed urine for himself, and could retain it for several hours. He was discharged, and some time after readmitted with calculus pyelitis and cystitis, from which he died. Examination of the parts after death showed that the cavity in the prostate had contracted so as now to be only of the size of a walnut, whereas the tumour cut away had the dimensions of half an orange; practically, the whole of the prostate was removed; the parts removed, and also the bladder with its surroundings, were specimens preserved in St. Bartholomew's museum. He asked Mr. M'Gill as to the statement that the ureters could be entered by the finger palpating the bladder; such an experience was most unusual, and was opposed to the belief that under no circumstances did regurgitation take place from the bladder into the ureter.—In reply to Mr. Thomas Smith, Mr. BOWLBY said that the prostate was removed by Mr. Willett from outside the bladder.—Dr. BROADHURST thought there would still be a place for the operation suggested and practised by Sir Henry Thompson.—Sir HENRY THOMPSON, in reply, said he was much interested in Mr. M'Gill's operation, and gratified by its results. This procedure was indeed a fresh starting-point, and he should further inquire into it. He, like Sir William Ferguson, had in three recorded cases removed large portions of prostate in cases of stone. All the urine had been withdrawn by catheter in the cases in which the suprapubic operation was performed. It was not the size of the prostate that constituted the danger. A small hypertrophy might cause the greatest interference with micturition, and consequent distress. Though an enlargement be enormous, yet retention might rarely be present. In neither of the three recorded cases had there been the slightest improvement in the patient's powers of micturition or in his general comfort. They had to resort to the catheter as before operation. It was of no use to remove a large prostate of many years' standing, because the bladder had then become a mere membranous sac, not possessed of any contractile power. But in earlier

Digitized by Google

cases, as in Mr. M'Gill's, before the bladder was atonied, there was an opening for the operation of prostatectomy; he said this without endorsing the operation, which must rest its claims to recognition on its success in the future. He was disposed to think that the suprapubic method was better than the perineal for the removal of the enlarged prostate in suitable cases. He considered that the vulsellum was a clumsy instrument for the removal of portions of the prostate—this in way of criticism of Mr. M'Gill's cases. The clean-cutting instrument would be better. As to the objection to operating in the presence of fetid urine, Sir Henry said that this phenomenon was solely due to decomposition in the bladder, and that usually after draining this organ the urine in a few hours became sweet.—Mr. M'GILL, in reply, spoke of the difficulty of getting portions of the prostate away; hence he had not been able to preserve any but minute fragments, which were microscopically examined in the first case recorded, and found to be true hypertrophy of the prostate. He should devise a special pair of curved scissors with long handles, so that in future he proposed to divide the prostate into two halves and cut portions away with a clean incision. He was satisfied that prostatectomy could be done, but he himself was not sure as to which was the best way to do it. He should not employ the perineal method of removal. Doubtless Sir Henry was right in placing a limit of time after which the operation would prove useless, as the result of the atony of the bladder consequent on the long-standing prostatic disease. A drainage tube of celluloid would be less expensive than a silver tube.

MEDICAL SOCIETY OF LONDON.

Fæcal Anæmia.

AN ordinary meeting of this Society was held on Monday, Nov. 14th, at 8.30 P.M., Dr. Hughlings Jackson, F.R.S., President, in the chair.

Sir ANDREW CLARK read a paper on the Anæmia or Chlorosis of Girls, occurring more commonly between the Advent of Menstruation and the Consummation of Womanhood, which appears in full on p. 1003.—Dr. BURNEY YEO said he considered too little stress had been laid on improper feeding as a cause of this condition. He had observed cases in which there were exacerbations of fæcal absorption indicated by rise of temperature, with languor and prostration.—Dr. DE HAVILLAND HALL thought that the frequency of chlorosis in young females and its rarity in males of similar age pointed to the generative system as being primarily at fault.—Dr. THEODORE WILLIAMS admitted that constipation was one cause of anæmia, but it was not an invariable accompaniment of that condition; on the other hand, the French who were habitually constipated, did not suffer to any great extent from anæmia, and he had met with many cases of constipation in young girls who were otherwise healthy.—Mr. S. BENTON advocated small enemata of rhamnus frangulæ mixed with lemon juice, glycerine, and alcohol as an easy and rapid method of removing fæcal accumulations.—Dr. ROGERS had found the majority of these cases accompanied by menstrual irregularity.—Dr. EDIS recommended treatment by a mixture of iron, aloes, and nux vomica, combined with out-door exercise.—Sir JOSEPH FAYRER said that the form of anæmia he most frequently had to treat was dependent on splenic cachexia. As a purgative he had found the sulphate of magnesia or soda of the greatest value.—Dr. HINGSTON FOX had met with similar cases in middle-aged women with "earthy" complexions. In them the cause was obviously fæcal accumulation.—Dr. THOROWGOOD had great faith in a combination of aloes and myrrh with iron.—Dr. HUGHLINGS JACKSON mentioned some observations by Bunge and Strümpell. The former pointed out that iron in ordinary food exists in a very complex organic combination—hæmatogen. Strümpell suggests that inorganic salts of iron are useful in anæmia, by protecting the hæmatogen from decomposition by sulphides in the alimentary canal.—Sir ANDREW CLARK, in reply, said that, though the appetite was sometimes capricious, it was often very good. A daily evacuation of the bowels was often unattended with adequate fæcal relief. He regarded accumulation of fæces in the rectum as only a local and mechanical evil, but it was the retention of fæces in the colon that gave rise to constitutional symptoms.

OPHTHALMOLOGICAL SOCIETY.

Brain Disease with Hemianopia.—Iridectomy in Relapsing Iritis.—Quiet Iritis.

AN ordinary meeting of this Society was held on the 10th inst., Mr. J. Whitaker Hulke, F.R.S., President, in the chair. A manuscript copy of the library catalogue, prepared under the direction of Mr. Adams Frost, was laid on the table.

Dr. SEYMOUR SHARKEY read a paper on a case of Cortical and Subcortical Disease of the Occipito-angular Region producing Hemianopia. The patient was a hawker, aged twenty-nine, who had suffered for twenty years from ordinary epilepsy, and since from epileptic insanity. In October, 1866, he struck his head with a piece of wood on the vertex of the skull; the wound left a scar, and since that time he had not been able to use his right hand, and the right leg was noted to be weak; the right hand is said to have been rigid since, and to have gradually lost sensation. On Dec. 17th he had a fit, and was brought into St. Thomas's Hospital. His pupils were dilated and unequal, the right being the larger. There were clonic spasms of the facial muscles and rigidity of the right arm and leg. He recollected the events of the fit, and had not bitten his tongue. There was hemianæsthesia in the right side, including the special senses on the same side. Optic neuritis developed. On Dec. 11th there was right lateral hemianopia. Death occurred on Feb. 1st, 1887, and was preceded by headache, insomnia, mental dulness, passing into coma. The temperature, though previously normal, rose on the last three days before death, and reached 107·4° F. just before death. At the necropsy, a tumour, which proved to be a round-celled sarcoma, was found in the left cerebral hemisphere beneath the cortex, and occupying the occipital lobe and part of the parietal lobe. The convolutions of the anterior half of the occipital lobe, the superior parietal lobule, and the upper extremity of the angular gyrus were thinned. The posterior part of the internal capsule was not invaded, but the growth extended nearly up to this sensory crossway. The question of the relation of ordinary epilepsy to so grave a disease as cerebral tumour, and whether the conditions of the former predispose to the latter, was only mentioned to be passed by for the present. Dr. Sharkey was not clear as to the cause of the partial right hemiplegia, but considered that the growth may have damaged without invading the arm centres. The growth had involved part of the leg centres in the superior parietal lobule. The optic neuritis was ascribed to the chronic thickening of the meninges at the base of the brain (another feature of interest was the thinning of the cranial bones, especially at the base). The homonymous hemianopia was ascribed to the destruction of the cortical and subcortical region of the occipito-angular region. The extensive destruction was parallel with the experimental facts determined by Ferrier, who observed that the lesion must be extensive and complete to produce a permanent ocular defect. The concentric contraction of the visual fields was probably due to the optic neuritis. The hemianæsthesia was set down to the damage to the fibres which go to make up the sensory crossway, but which had not yet entered the posterior third of the posterior limb of the internal capsules. Therefore the hemianæsthesia and the hemianopia may be ascribed to damage of the sensory radiations into the temporo-sphenoidal and callosal regions, and the optic radiations of the occipito-angular region. Dr. Seymour Sharkey also read the sequel to the case of hemianopia recorded by him in the fourth volume of the Transactions of the Society, p. 276. The patient had had a series of epileptic fits associated with visual phenomena, and almost certainly due to discharges commencing in the motor cortex, and spreading thence into the visual area or occipito-angular region. In December, 1886, all signs of paralysis had disappeared, but the area of blindness remained practically the same as before (Nettleship). This case was like other cases of hemianopia that Dr. Sharkey had seen, in that the symptom persisted for a long time without change, and without being associated with other morbid nervous phenomena.—Mr. NETTLESHIP could call to mind at least four cases of hemianopia which remained stationary for at least three or four years. In one case of a man the hemianopia had lasted at least ten years, and there was perhaps a peculiar intellectual state, for the patient invariably denied having been

Digitized by Google

seen previously.—Dr. KEALL had not observed special mental defects in cases of hemianopia.—Dr. J. ANDERSON thought that some cases were accompanied by mental change, and others were not; perhaps hemianopia of cortical or subcortical origin was more likely to be accompanied by mental alterations.—Mr. NETTLESHIP referred to cases of hemianopia of sudden onset, and apparently due to basal lesions, and asked how such cases were to be explained.—Dr. SHARKEY, in reply, said that in the case of which he had read the sequel, the conclusion might legitimately be drawn that the hemianopia was of cortical origin. He had not observed alterations in the veracity of hemianopic patients. If the hemianopia were due to basal lesions, the other sensory fibres lie so closely to those which subserve vision that they could hardly escape; nevertheless, affection of the special and other senses might be overlooked; and later in the cases compensation might have been established.

Mr. NETTLESHIP read a paper the object of which was to obtain as close a definition as possible of cases of Relapsing Iritis in which there was reason to think that iridectomy would have the effect of preventing further attacks of the disease. It was shown that relapses of iritis were due much less to the presence of adhesions than to the constitutional cause of the disease, since syphilitic iritis did not relapse, whilst forms of rheumatic inflammation of the eye without iritis relapsed in exactly the same way as rheumatic iritis. Putting aside as usually unsuitable for iridectomy cases with keratitis punctata, and cases where the iris was very extensively adherent and yet softened (parenchymatous iritis), and regarding cases as unfavourable which were complicated with high myopia; and, on the other hand, assuming the necessity of the operation in cases where iritis with circular synechia had led to bulging of the iris,—the operation was next considered as preventive of future active attacks rather than of the consequences of past disease. In this relation he believed that whilst the effect of iridectomy in preventing future attacks of iritis had, chiefly owing to Von Graefe's teaching, been considerably overrated, the operation, in properly selected cases, very seldom did harm, and sometimes undoubtedly did good. Observation of cases not operated on showed, however, that very long intervals occurred between successive attacks, and that the disease tended to wear itself out with time; whilst, on the other hand, it was not uncommon to meet with cases which had relapsed as much after iridectomy as before. Taking into account these and other sources of error, the conclusion was arrived at that iridectomy for recurrent iritis should be resorted to only after a very patient trial of all other means of treatment. Cases were given in illustration of all the more important statements.—Mr. PRIESTLY SMITH doubted from his own experience whether Von Graefe's dictum was generally true. When glaucoma seemed imminent he would perform iridectomy, but till then treat the cause of the iritis. Salt baths, acting on the skin, were perhaps the best means of treatment in these cases of recurrent iritis—better than mercurials and other alterative treatment. A tonic treatment, with change of air at Droitwich, with its salt baths, was very good. Iridectomy was powerless to cut short the tendency.—In reply to Mr. Juler, Mr. NETTLESHIP said that in cases of serous iritis, with keratitis punctata, he thought iridectomy was not required; and in other cases where the iris was infiltrated, the iridectomy was not likely to prove of benefit. In cases where complete adhesion forms a circular synechia, iridectomy was called for, and generally did good. But he could not say which cases of relapsing iritis would, and which would not, be benefited by iridectomy.—Mr. J. HUTCHINSON, jun., related several cases of Quiet Iritis, in which the attack, sometimes leading to extensive adhesions to the lens, and involving much deterioration of sight, was from the first unaccompanied by the typical features of inflammation. It was, perhaps, not sufficiently known that iritis in certain cases did not reveal its presence by the characteristic frontal pain, and was practically unattended by congestion or photophobia, though the fact had been pointed out by various ophthalmic surgeons. He had tabulated thirty-seven examples of quiet or insidious iritis, and from these deduced the following conclusions: 1. Sympathetic inflammation, congenital syphilis, and inherited arthritic (gouty or rheumatic) tendency are probably the most frequent causes of quiet iritis. 2. This form is very rare in the iritis of acquired syphilis, that of the ordinary rheumatic type, and in traumatic or herpetic iritis. 3. Sex and age have little or no influence in modifying the severity of the symptoms accompanying iritis. 4. That a constitutional tendency cannot always be invoked as the reason for iritis taking on an insidious form is shown by the occasional occurrence of two attacks in the same patient, one being accompanied by violent inflammatory symptoms, the other perfectly quiet throughout. 5. The absence of the ordinary symptoms of iritis by no means always implies a mild course of the disease, some of the cases going on to complete blindness of the affected eye.—Mr. J. B. LAWFORD said that it would be difficult to tell whether the quiet iritis were relapsing or not, if the pigmentation on the lens were the chief evidence of past mischief. Cases might originate congenitally or even during intra-uterine life.—Mr. HUTCHINSON, in reply, thought that the cases might originate during intra-uterine existence; in one case a traumatism was the cause; but the iritis was silent, and was only manifested after the use of atropine by the presence of uveal pigment on the back of the lens.

The following living and card specimens were shown:—

Mr. QUARRY SILCOCK: Case of Choroido-retinitis with Opaque Nerve Fibres and Keratitis Punctata.

Dr. POULET WELLS: Localised Secondary Pigmentation of Retina in Distribution of Plugged Branch of Central Artery.

Mr. KEALL: (1) A case of Congenital Small Lens (?)—Mr. Juler considered that the lens was present of usual size, and on its posterior surface there was an opacity. (2) Semicircular Hæmorrhage, not at the Macula Lutea.

Mr. DOYNE: Recurrent Œdema of Upper Eyelids in a young woman who had not menstruated; it had lasted fourteen months; megrimous headache had appeared for the last two months.

Dr. MULES: (1) An Evisceration Scoop; (2) an Instrument for Inserting the Artificial Globe used in his method of operation. Made by Mr. Armstrong of Manchester.

Mr. JULER: A new Apparatus for Illuminating the Perimeter.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

President's Address.

A MEETING of this Society was held on Nov. 9th, R. Thorne Thorne, M.B., F.R.C.P., President.

In dealing with the subject of the Progress of Preventive Medicine during the Victorian Era in his inaugural address to the Society, the President expressed the opinion that there were but few phases in the great progress which had marked the Victorian era that had had a greater effect for good than that which had been concerned with improvements affecting public health, and he contended that intelligent action in this direction had been largely based on the development of preventive medicine and epidemiology. Up to the date of the Queen's accession the first requisite to a proper understanding of the etiology of disease—namely, the registration of the causes of death—was wanting. With 1836 came the civil registration of deaths, and at once some insight was acquired as to the incidence of disease on condition of life and locality; and between 1838 and 1840 it became evident that wide-spread epidemics of small-pox, scarlet fever, and "fever," a generic term including all our continued fevers, were prevailing. It was also found that in English towns and cities the general mortality was greater by 44 per cent. than in country districts, and that this excess was largely capable of remedy. Tracing the history of certain preventable diseases during the past fifty years as typical of the progress made, reference was made to the adoption in 1840 of the system of public vaccination, by which "all persons" could claim to be vaccinated at the public cost, and it was shown stage by stage how it was reserved to this era to extend and elaborate that system under the Vaccination Acts passed between 1853 and 1871. The effect of these various statutes was discussed, and it was shown that whereas in the quinquennium 1838-42 the small-pox mortality of England was 57·2 per 100,000 living, it steadily fell to 14·4 during the period 1865-69, an achievement without parallel in the history of sanitary medicine. But then came the sudden rise during the period 1870-74 to a rate of 42·7. Discussing the various causes of this fatal epidemic, Dr. Thorne Thorne alluded to the immunity to attack from infection which is believed to be inherited by the offspring of those who have themselves suffered from certain infectious fevers, and he thought it possible that, just as the Fiji islanders were decimated by measles, against which

Digitized by Google

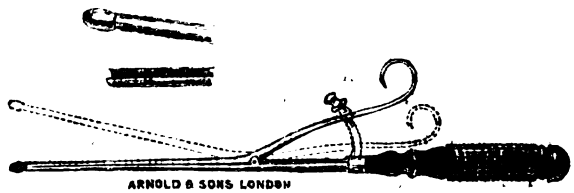
they had acquired no sort of protection by heredity, so the people of this country lacked, in the face of a poison of exceptional virulence, and by reason of their ancestry being vaccinated, that partial protection against small-pox which they might otherwise have inherited. But it was, above all, proved by the researches of Dr. Buchanan that the epidemic had been brought about by excessive trust in vaccination as such, without regard to the quality of the protection given, and it was abundantly proved that the potency of a comparatively recent vaccination can hardly be exaggerated. With improved practice in vaccination methods, the small-pox death-rate has again continuously decreased, until in the five years 1880-84 it stood at 6·5 per 100,000, a far smaller rate than any attained since records of this fatal disease were commenced. In dealing with typhus fever, its wide diffusions in our large towns and cities during the earlier portion of Her Majesty's reign were recalled, and it was explained how this disease had always been associated with the crowding together of houses on area and of people in dwellings; these conditions being invariably associated with a state of destitution, and leading to that fouling of air breathed which results from the concentration of the emanations from human bodies. Turning to the early history of the city of London, it was pointed out how in such places typhus was found to be a habitual pestilence, our fever wards being filled from their midst. Gradually the fact was recognised that the great enemy to typhus was free movement of air, and then came the wholesale destruction of unhealthy property, the carrying of great thoroughfares through the densest aggregations of houses, and the opening up of breathing-spaces—a task to which the Metropolitan Board of Works have already devoted over fourteen millions sterling. Some millions have also been spent by official and unofficial bodies in erecting wholesome homes for artisans and labourers. Until 1869 typhus was not separated from the deaths due to the continued fevers generally, but before that date a substantial reduction of deaths from fever had already been effected, and whereas in that year the typhus death-rate for England was 1·9 per 10,000, it had now fallen to 0·1. The story of Liverpool typhus was next discussed, but, with all its progress, that city had never got rid of its houses densely built together, back-to-back and overcrowded, and Liverpool still formed the principal centre for typhus in England. Coming next to typhoid fever, special prominence was given to the great results which followed on the final differentiation of this disease from typhus by Sir William Jenner. Then for the first time, works, hitherto carried out largely with a view to prevention of nuisance and generally in the interests of health, could be adopted intelligently and with the intention of coping with a specific infection. And, later on, the operation of the infection was traced to channels always operating through the agency of filth, but which so far had remained undetected. First came Dr. Ballard's discovery of the communication of typhoid through the agency of a milk supply; frozen creams and ices were found to act as vehicles of the infection; intermittent water-services led to its distribution; and the potency of the infection was found to be such that, even when present in potable water in quantities that were infinitesimal and altogether beyond the reach of discovery by chemistry or physics, it could, as in the Caterham epidemic, lead to widespread disaster. Steadily, with an expenditure based on the lines indicated by these discoveries, have the deaths from typhoid fever diminished, and between 1869 and the present date the rate per 10,000 has fallen from 3·9 to 1·7. In a similar way the progress of our knowledge in the prevention of scarlet fever, diphtheria, phthisis, and cholera was considered, and especial prominence was given to Mr. Power's recent researches as to the connexion which existed between scarlet fever in man and a corresponding disease in milch cows. In scarlet fever a definite micro-organism common to man and the cow had already been discovered; and diphtheria was known to have certain relations to an allied animal disease, and there were observers who believed that phthisis in man had concern with the use as food of the flesh and milk of tuberculous animals of the bovine tribe. The story of the past fifty years was one in which the principles of preventive medicine had been applied to the unravelling of the actual sources of disease, and in the case of many communicable affections their cause had been traced to organisms, definite in character, always breeding true, and having known habitats. The results were shown by the significant lessening of the general mortality, and of both death and sickness from the more preventable diseases—results which necessarily involved an improved vitality and a greater power for remunerative work among the living. The work of disease prevention during the Victorian era had proceeded on a scale that it would be difficult to define, but it can be in part measured by the influence it has had in sweeping away much of that misery which is the harder to bear because its cause is preventable, in elevating the condition of our fellow men, and in bringing health with its attendant happiness and prosperity to an untold number of British homes.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Medico-Psychologica Association was held at Bethlem Hospital on the 11th inst. There was a large attendance of members, under the presidency of Dr. Needham.

Dr. SAVAGE read notes on the International Congress in Washington; and Drs. BLANDFORD and MICKLE also reported their observations after attending the Congress, the Medico-Pyschological Section of which seemed generally admitted to have been very successful.

Dr. R. PERCY SMITH exhibited the brain of a young case of Pachymeningitis.



Several new members were elected; and a further donation of £340 for scientific purposes was reported to have been made by members of the family of the late Mr. Gaskell.

Dr. WHITE read a paper on Athetosis connected with Insanity, communicated by Dr. Greenlees.

New Inventions.

NEW UTERINE DILATOR FOR RAPID EXPANSION OF CERVICAL CANAL.

THIS instrument will, I believe, be found to supply a want long recognised by gynæcologists—namely, that of a reliable and effective means of securing the rapid and permanent dilatation of the cervical canal in the treatment of stenosis giving rise to dysmenorrhœa, sterility, &c. The principle on which it is constructed differs from that of other dilators in producing expansion of the canal from within outwards—in other words, in imitating the natural process of expansion from the uterine cavity downwards to the os uteri; whereas

other dilators, such as Hegar's &c., act in the opposite direction. In my own hands the utility of this instrument has been fully tested in a large number of cases of sterility and dysmenorrhœa in my hospital and private practice, and the method of its employment in such cases is fully described in a paper "On the Treatment of some forms of Sterility," which I recently read at the Dublin meeting of the British Medical Association. I may add that the instrument may also be used with advantage for the dilatation of the female urethra in many cases in which this procedure is indicated. This instrument has been most carefully made and artistically finished by Messrs. Arnold and Sons, West Smithfield, London.

THOS. MORE MADDEN, M.D., F.R.C.S. Edin.,
Obstet. Phys. and Gynæcologist, Mater Misericordiæ Hospital, Dublin, &c.

VACCINATION GRANTS.—Mr. Felix Jones, M.R.C.S., of Llanfyllin, Montgomeryshire, has received for the second time the Government grant for efficient vaccination.—Mr. W. D. Jefferson, of No. 1 District, Ripon Union, has obtained the grant (third time) for vaccination in the above union.

ROYAL COLLEGE OF SURGEONS' SUPPLEMENTAL CHARTER.

DEPUTATIONS, FROM FELLOWS AND MEMBERS TO THE LORD PRESIDENT OF THE PRIVY COUNCIL.

[AN abstract of the following report appeared in our Second Edition of last week's issue, published at 6 P.M. on Friday.]

DEPUTATION OF FELLOWS.

ON Friday, the 11th instant, the Lord President of the Privy Council received a deputation from the Association of Fellows of the Royal College of Surgeons, consisting of Mr. Pollock, Mr. Swain, Mr. Timothy Holmes, Mr. J. Couper, Mr. Bruce Clarke, Mr. A. Norton, Mr. A. Willett, Mr. Macnamara, Surgeon-Major Smith, Mr. Alban Doran, Mr. Wickham Barnes, Mr. Wakley, and others.

Mr. POLLOCK, in introducing the deputation, said he did not know whether his lordship was familiar with the Charter granted to the College of Surgeons in 1843; if not, he would shortly call attention to the alterations made by that Charter. Prior to 1843 the Council of the College was self-elected, and the College consisted merely of Members. The Council consisted of twenty-one members, and they conducted all examinations. In 1843 a new Charter was applied for, and some very important alterations took place. The Charter provided that the Council should consist of twenty-four members to be elected by a body that was then established termed Fellows, in addition to the Members. That body of Fellows was in the first instance established by the nomination of a certain number of names without any examination or without any fee. The total number nominated was about 300; the names were submitted to the proper authorities, and the Fellowship was accordingly conferred. The body of Fellows had one privilege granted to them—namely, that for the future they should elect the Council. The Council was no longer to be self-elected, and the members remained in office until resignation or death; but whenever a vacancy occurred the Council was recruited by Fellows at a general election. After the 300 Members were nominated there was a second list of about 150 or 200 added to the original number without examination or fee, but on nomination of the Council. Subsequently to that period every Member of the College who was not included in this list of Fellows was compelled to pass an examination and to pay a certain fee. He was himself one of those unfortunate individuals. He had only been a Member of the College a few years, and on his return from a foreign journey he found himself in the predicament of being compelled to set to work to pass an examination and pay a fee in order to take the position of surgeon at St. George's Hospital. It was considered by many of them a great injustice that a large body of Members, some 15,000 in number, should be placed in an inferior position, while a certain number, by selection as it were, should be placed in a superior position. That consideration had more or less influenced him in never attempting to enter the Council of the College, because he thought that a great injustice had been done, and he had resisted all solicitations to enter the Council, although he had held the position of surgeon at St. George's Hospital for many years. The Council was elected by the Fellows, and had the management of everything connected with the College, all its general arrangements, its examinations, and its finances. They called a meeting of the Fellows once a year, at which they made a statement of the general work of the College, but the Fellows had no power or authority to interfere in any way, to alter anything, or to express any opinion with regard to the conduct of the College during that time; in fact, they had no share in the management of the corporation. He was happy to say that there were present in the deputation several distinguished members of the profession. Mr. Holmes, senior surgeon of St. George's Hospital, was present as a past examiner and a past member of the Council, and had he retained his seat in the Council (and they would all have been glad if he had done so), he would probably by this time have been President of the College. There were also present two members of the Council, Mr. Macnamara and Mr. Willett, and he had a letter from a past member and another from a present member of the Council, who entirely approved of their proceedings. A few years ago a new Charter was contemplated by the College, and in consequence of that Mr. Swain of Plymouth proposed a certain number of resolutions at an annual meeting of the College. As that gentleman was the proposer of those resolutions, he thought it would be better for them to be represented by him on the present occasion, and he would therefore call upon Mr. Swain to take up the subject.

Mr. SWAIN said that as one of the originators of the movement, which, as his lordship was aware, was to increase the power and the rights of the Fellows and Members of the College, it fell to his lot to address his lordship, and he would do so very briefly upon one topic only. It had fallen to his lot in March, 1884, to move the following resolution, which would indicate the spirit by which the Fellows and Members were moved: "That it is desirable that no alteration in the condition or relations of the College shall be effected without the consent of the Fellows and Members convened to discuss such alteration. That there shall be an annual meeting of Fellows and Members at which the annual report shall be presented, received, and adopted." That resolution on that occasion, and he believed on two other occasions, or at any rate one exactly similar, was carried unanimously. At those meetings the President and Council of the College had sat quietly by, having made no motion in any shape or form, and they simply rejected all overtures which were made to them in the direction of the resolution. The position in which the Fellows and Members were placed had already been stated. They were annually called by the College to meet from all parts of the metropolis, and from all parts of the United Kingdom. The report was laid before them, but it was nothing more or less than the minutes of the meeting of the Council. The Members were allowed the right of speech and the right of meeting, but they had no power to modify the report in any way or to shape the action of the Council. It appeared to him and to all concerned, and he ventured to think it would also appear to his lordship, that to call together a number of men from all parts of the kingdom who were certainly not the least educated portion of the community, and to ask them to come and hear a report read about which they knew everything already, and to give them no power whatever to adopt the report, to reject it, or to modify it in any way, was, to say the least, exceedingly puerile. What they especially asked for was that, as Fellows and Members of the College, they might have some power in the management of the College. Year by year the College was becoming more and more important, not only as an educating body, but also as a spending body. They had a very large sum of money at their command, and although the Members had perfect confidence in the twenty-four gentlemen who constituted the Council, it was not in the nature of things that a power of that sort should be vested in the hands of twenty-four gentlemen who were entirely irresponsible to anybody, either for the management of the College or for the expenditure of the very large sums of money entrusted to them. It was not at all in accordance with the spirit of the times, and the deputation sincerely hoped that in any consideration of the new Charter some greater powers would be conferred upon the Fellows and Members in the management of their own College. He thought he was right in saying that had the Council met them upon a single point with anything like liberality or with any desire to concede the point to them, the agitation would not have proceeded to the extent to which it had gone—an extent far beyond the limits which they had originally contemplated.

Mr. TIMOTHY HOLMES said he had been asked to say a few words as the mover of the resolution which he had the honour of forwarding to the Lord President at the general meeting of the College of Surgeons held a few days ago, and also as having served the College in a great variety of capacities—he might say in every possible capacity except that of president; and, if he might say so much about himself, it was in consequence of his disapproval of the way in which the election of president was managed that he ceased to be a member of the Council. He was happy to think that the movement in which they were concerned was largely supported even by the members of the Council of the College themselves, two of whom were present with the deputation in order to support the general objects for which the Association was founded. Those general objects had been ex-

Digitized by Google

plained by Mr. Swain. The original resolutions on which the Association was founded were four in number. The first was, "That in the opinion of this meeting it would materially conduce to the welfare of the College that the Fellows and Members should be invested with a larger share of its management." The second resolution was, "That it is desirable that no alteration in the constitution or relations of the College should be effected without the consent of the Fellows and Members convened to discuss such alteration." The third was, "That there should be an annual meeting of Fellows and Members, at which the annual report should be presented, received, and adopted." And the fourth was, "That at such meeting the president for the ensuing year should be elected by a majority of the Fellows present." It was on those lines that the Association of Fellows was formed, and it comprised about one-fourth of the whole number of Fellows of the College, a very large number when they considered that men in practice were very little disposed to join in any such questions as these, which really did not very much bear upon the immediate needs of professional life. He submitted, as a proposition that must commend itself to the common sense of everyone, that it was an anomaly that a great institution, consisting of at the very least 13,000 perfectly educated and well-cultivated men, should be entirely at the mercy of twenty-four of their number. It was a thing which was never contemplated by the original Charters. It was perfectly evident in the original Charters, to which that of 1843 was only a supplement, that Members were intended to take an active share in the management of the College, and were, in fact, the governing body of the College. That, however, had been entirely set aside, and since the Charter of 1843 the Members had had nothing whatever to do with the management. They were treated as having exactly the same rights or no rights as persons actually strangers to the College; and the Fellows themselves, who were created by that Charter, had no power whatsoever, except that of coming to the College once a year and voting for the members of the Council—beyond, of course, admission to the College, and to the examinations and other functions which took place therein, and which naturally they could not be deprived of. That was an anomaly, even comparing it with a body so strict in its management as the neighbouring College of Physicians, for there the Fellows of the College had that control over the proceedings of the Council which was the natural privilege and almost the right of Fellows of a College. He could not understand for what reason the Council of the College should be invested with an absolute and arbitrary discretion over the great property which had been accumulated, partly by the contributions of Fellows and Members, and partly by the bequest of a gentleman, whom his lordship might have known, and who had recently left the College a very large sum of money. He did not see why all this influence, all this power, and this great institution should be entirely in the hands of a Council with no control whatever on the part of any other person, so long as they confined themselves to professional objects. They were all willing to treat the Council with that respect which was their due, and they were not there to charge them with anything like corruption or malversation, or anything of the kind, but he repeated that they disposed of this money and of their great influence in a way which deprived Fellows and Members of what, he submitted, they ought to have—namely, some right of management in their own College. The Council of the College proposed in their petition for a new Charter to do certain things. In the first place, in respect to the Fellowship, in direct defiance to the wishes of the Fellows as they had been formulated on many occasions, and not only of the Fellows, but of the Members also, they proposed to empower the Council to elect to the Fellowship Members of twenty years' standing, not exceeding ten, instead of two, in each year. That was really a proposal to revive the old order of Fellows by election, which Mr. Pollock had referred to, and to perpetuate an abuse which had been protested against by all the Fellows by examination from the time that it existed. There was a reason for its existence originally. At that time the order of Fellows was new, and it was thought right that any Member who was a Member in the year 1843 should have admission into the new order. Whether that was right or not he did not say, but there was no reason for it at the present time. The Fellowship examination was a thing which they were proud of. It was the first examination, the first qualification for surgeons anywhere. They protested most strongly, and would continue to protest in every legitimate way, against anything which would discredit this diploma. That his lordship might see how strong the feeling of the profession was on that subject, he would refer to a resolution passed at a late meeting of the Fellows and Members of the College on this very subject. That was a meeting held on Nov. 4th, 1886, and the resolution that was carried was this: "That in the opinion of this meeting the first method recommended by the Council for widening the basis upon which the Fellowship is obtained tends to lower the academic status of that diploma, and in the interests of surgical education is not advisable." That referred to a proposal which, if not identical with the present one, was the same to all practical purpose, and the resolution he had read was proposed, not by a Fellow of the College, but by a Member, seconded by another Member, and carried by acclamation by the Members present. He protested most strongly, in the name of the Association of Fellows, against that clause of the new Charter, and begged his lordship to give it his most serious attention before he proposed to recommend Her Majesty to assent to the prayer of the College. And what he said of that clause, he would say still more strongly, if possible, about the one preceding it, which was to enable the Council to determine by rules and regulations, instead of, as at present, by bye-laws, the condition of admission to Fellowship by examination. He said that that proposal ought to be entirely excised; that one of the great safeguards the profession now had against the tampering with the Fellowship, to which some members of the Council showed so strong a disposition, was that they could not do it by resolution; and, if he was not wearying his lordship, he would give a very strong example of the fact. It was not many years ago since he was a colleague of the present President of the College, Mr. Savory, and another gentleman, who he was sorry to say was now deceased (Mr. Cooper Forster), in the Court of Examiners, when it came to their knowledge, quite casually, that a proposal was being passed through the Council which they considered derogatory to the examination for the Fellowship of the College of Surgeons. A very short time was given before the next meeting of the Council, at which this bye-law would have been affirmed and passed, so far as the College could pass it, and would have been submitted to the Secretary of State, who, being probably not in possession of sufficient information, would in all probability have passed it as a matter of course. They exerted themselves to the utmost—Mr. Savory, Mr. Cooper Forster, and himself—and addressed every Fellow by examination who was at that time accessible in England. The result was, they made so strong a protest on the subject that the Council of the College at the last moment rescinded the decree, and the proposal was no more heard of. But if the proposition which was now made had then been in operation there would have been no such opportunity; the Council could have passed it at one meeting and confirmed it at the next, before the matter was laid before the public at all. He was sure that he would have the support of all the Fellows of the Association in protesting most strongly against those two clauses of the revised Charter. Mr. Swain had alluded to the way in which the Council determined and disposed of the very large funds which were now in their hands, and on that subject he would therefore say nothing further, except to protest in the strongest way against any such power being left in their hands. But there were other matters on which the feeling of the profession was even stronger. For instance, the Council of the College, joining with the College of Physicians, had established a new examining body, to which they had not the slightest objection. He was a member of the Council when the matter was carried through, and thought it was a wise and good step, and one in the interest of the profession, but at the same time a step of that kind ought not to have been taken without the profession having the opportunity of pronouncing their opinion upon it, and no professional body was so competent to pronounce an opinion upon it as the Members of the College of Surgeons themselves. The Fellows of the College of Physicians had, as he had mentioned, a privilege which the Fellows of the College of Surgeons did not possess in this matter. But besides that, the Council of the College had taken a step which was very much more questionable and arbitrary. They had excluded from that league of theirs with the College of Physicians the Society of Apothecaries, and by that exclusion they had set up in London a second examining body. Now, if there was one thing on which professional feeling

Digitized by Google

was more strong than another, it was that there should not be a plurality of examining bodies, and the College of Surgeons had done that in spite of the protest of the General Council itself. The General Council begged the College of Surgeons to reconsider their proposal, and they would not do so. That showed the absolute control which the Council of the College of Surgeons affected to have over matters that ought to be matters of common interest to the whole profession. The same thing might be said with regard to granting degrees. The College of Surgeons proposed to join the College of Physicians in making some arrangement for the granting of medical degrees, and they had never ascertained what the feeling of the present practitioners of medicine was upon the subject, and even if they had ascertained it they would not have taken the smallest notice of it. He wished to refer to the election of president, a matter which had touched his feelings very strongly, and also those of his old friend and instructor, Mr. Pollock. It used to be the habit at the Council of the College of Surgeons simply to hand this office round from one man to the next. That became such a mere matter of routine that it degraded the office of president, and, in fact, very few people knew who the president of the College of Surgeons was. That matter was one which required not so much the intervention of any public authority as a full and free discussion between the Council of the College and their constituents. They did not ask his lordship to interfere in a professional matter, which must necessarily be somewhat obscure to him; but they asked him to remit those matters back for consideration in order that there might take place—what had never yet taken place in the history of the College of Surgeons—a full discussion between the governing body and the body that it governed, in order that they might state plainly their proposals and the reasons for their proposals, and that they might hear any objections that might be raised to them. They were not certainly destitute of experience or information on those matters; they were not violent agitators or revolutionaries; they were perfectly prepared to meet together and to settle those matters in a friendly way with friends such as they regarded the Council of the College to be. They thought, however, that to attempt to settle this off-hand by the mere motion of a majority of a couple of dozen men with whom they were never able to have any intelligent discussion was an absurdity, and they confidently hoped that Her Majesty would be advised to remit this proposed new Charter for reconsideration and for discussion. There was only one other matter on which he wished to speak, and that was with respect to the claims of the Members. They were all Members of the College as well as Fellows, and their Association, as an Association, backed up the claims of the Members to a fair and reasonable share in the management of the College. He perfectly allowed that Fellows by examination ought to have the leading share in a body which was to a very great extent educational, but they said as that body ought not to be entirely educational, so the Members ought to have a fair share in its management. As an Association they had backed up the claims of the Members, but there were some of them who did not take that view. Those of the Fellows who did take that view would join the deputation of Members, and it was partly for that reason that they had asked that they might be received separately.

Mr. TWEEDY said he did not know that he could add much to the statements just made, but he would call his lordship's attention to the difference between the practice of the College of Surgeons of England and that of other Colleges. In the King and Queen's College of Physicians of Ireland there were meetings of the Fellows every month. In the Royal College of Physicians of Edinburgh there were four quarterly meetings of Fellows, and extraordinary meetings of Fellows on the requisition of four Fellows. At the Faculty of Physicians and Surgeons of Glasgow there were ordinary meetings of Fellows resident in Scotland every month. At the Royal College of Physicians of London there were four ordinary meetings, and extraordinary meetings on requisition. At the Royal College of Surgeons of Edinburgh there were regular general meetings, and at the Royal College of Surgeons in Ireland, though the Fellows were not consulted by the Council, yet the Council was elected annually; so that really the Fellows had an effective power in the control of the management of the College. In the case of the Fellows of the College of Surgeons of England, Mr. Holmes and Mr. Swain would pardon him if he said he thought they had made their position rather more favourable than it was. They had absolutely no inherent right of meeting in the College whatever. (Hear, hear.) They had had two or three general meetings since the Association was formed, and in consequence of the representations made by it, but previously no Fellow and no Member, and no body of Fellows or Members, had, as such, any right whatever to hold a meeting or to call a meeting in the College. There was a bye-law framed in the year 1831 for the purpose of preventing such meetings in the College. The Members of the College in that year met at the Hunterian Oration, and some of them thought it a convenient occasion to protest against an order that had been given for the exclusion of navy surgeons from levées. The Council at that time endeavoured to, and did as far as it could effectually, suppress the meeting. A good deal of contention arose; but the consequence was that in May of that year the Council obtained a bye-law, which was still in existence, preventing all meetings in the College, except with the consent and approval of the president and the Council. That bye-law had, ever since, effectually prevented Fellows and Members from holding a meeting in the College, and yet, curiously enough, it was by that bye-law that they were now allowed to meet in the College. In the year 1869 Mr. Erichsen moved in the Council that Fellows and Members should have greater facilities for meeting in the College to discuss collegiate affairs. When the report was made, it was found that this bye-law, which had been framed to exclude Members and Fellows from such meetings, was sufficiently elastic to allow them to meet. The bye-law stated that no business should be transacted or any matter discussed or debated at any meeting or assemblage convened by or under the authority of the president or Council, except the special business for which the meeting was convened. The meetings that had been convened had been meetings for the election of members of Council, for the delivery of lectures, and so on, but at those meetings effectual precautions had been taken to prevent the discussion, or even the mention, of any other subject whatever relating to the College. So that, so far from their having the right of meeting, they had no real right of meeting. In consequence of the representations of the Association of Fellows, they had been allowed lately to go to the College once a year to receive as read a report which, as a matter of fact, he believed, was printed and bound up in the College Calendar before the meeting was held. Such a proceeding was ridiculous and absurd. (Hear, hear.) One other point he wished to call attention to. A resolution had been passed by the Association, and unanimously approved by large general meetings of Fellows and Members held in the College, that no alteration should be made in the constitution or relations of the College, or in any bye-laws, without the consent of the Fellows and Members specially convened to discuss the same. In the Charters the Fellows and Members were called the body corporate and politic. But the Council, which was defined as being the governing body, had declined to accept this proposal. Before any person could be admitted as a Member of the College he had to make this declaration in the presence of an officer of the College: "I, A. B., do solemnly and sincerely declare that while a Member of the College of Surgeons of England I will observe the bye-laws thereof"; and then it was laid down that "every person prior to his admission as a Member shall subscribe his name to a copy of the bye-laws of the College in testimony of his having engaged himself to the observance thereof." They had therefore solemnly to declare to observe bye-laws which might be altered, rescinded, or added to without their consent and without their sanction—nay, even without their knowledge. They were members of the body politic and corporate, and yet the constitution of that body might be altered in many ways without their having any voice or control in the matter. It seemed to him contrary to every principle of equity and justice that one party to a solemn contract should be at liberty to alter the terms as they pleased (hear, hear), while the other party should have no power whatever of approving or disapproving. At present, though the Fellows had very little power, they did, as a matter of fact, nominally elect the Council; but the conditions under which that election took place were so prohibitive and restrictive that the Council was, as a matter of fact, elected by a very small number of persons. He had prepared a list, from which would be seen the number of votes by which the present members of the Council were elected.

Digitized by Google

At the head stood Sir James Paget, but with only 205 votes, while at the bottom of the list stood another member of the Council, elected by 101 votes. A member of the Council might therefore be elected by about 100 votes, and yet he then became one of twenty-four, or perhaps one of thirteen, who might have the absolute disposal of the affairs of the College of Surgeons, numbering, say, from 13,000 to 17,000 Members. In the College Calendar the number of Fellows for the year was given at about 1100, and the number of Members at 17,000. These numbers, he believed, were not strictly accurate. It was, perhaps, impossible to keep a strict Register, but, as a matter of fact, the Fellows, he believed, numbered about 1000, and the Members from 14,000 to 15,000; but 101 votes, as it seemed, might make a Fellow of the College a member of the Council; by this it would be seen how little representative the Council was of the great body of the profession.

The LORD PRESIDENT, in reply, said that what had been brought before him should receive his careful attention. As he understood it, their case practically came to this—that they wanted an alteration of the constitution of the Royal College of Surgeons, to make it a popular body to a certain extent, instead of being comparatively a close body. (Hear, hear.) That was the foundation of what they required, and he would look to the facts they had laid before him before coming to any decision.

Mr. TIMOTHY HOLMES asked the Lord President whether he would like this matter to be put in writing.

The LORD PRESIDENT said he certainly should like it to be in writing.

Mr. POLLOCK said he was sure he expressed the feelings of the meeting in thanking his lordship sincerely for the kindness with which he had received them.

DEPUTATION OF MEMBERS.

A very numerously attended deputation from the Association of Members of the Royal College of Surgeons then waited upon the Lord President with reference to the same subject.

Sir GUYER HUNTER, M.P., in introducing the deputation, said he did not intend to enter into any details, but would leave those to others who were more competent to speak upon them. He was in entire sympathy with this meeting; it had his hearty concurrence and best wishes. It did seem an exceedingly anomalous state of affairs that when the electoral franchise had been extended even to the illiterate classes of the country, a body of diplomatised Members of a College should not be allowed to exercise any influence in the affairs of the College from which they had their diplomas. In 1797 he was informed the Houses of Parliament threw out a Bill which failed to recognise the status and the position of the Members of the College with reference to the capacity to elect the president and to sit on the Council; and Lord Thurlow, in speaking of the Members, then said: "They have great cause to complain: their privileges have been violated; they have been too long trampled under foot, and they have the strongest title in the world to have their complaints heard with patience and attention." He was sure that the Lord President would give his patient attention to what would be laid before him, and hoped that it would end in the settlement of a question of great difficulty, and which had created a great deal of dissatisfaction amongst the members of the medical profession. (Hear, hear.)

Mr. HART read a long statement endeavouring to trace the succession of the College of Surgeons from the two guilds, the Company of Barber Surgeons and the Fellowship of Surgeons, existing in the early part of the fourteenth century. He referred to the various changes which had been made in the Charters of the College. After the Charter of 1843, he said that, with the exception of an unimportant Supplementary Charter in 1849, relating to the examination in dental surgery, no further legal change in the rights or constitution of the commonalty had been made down to the present time. An important practical change, however, had taken place as to the customary annual meetings of all the Members. These did not appear to have been held in the bad times following 1784, although the body of Members successfully asserted their right to meet and act in connexion with the petition against the Bill of 1796–7; but with the exception of an important meeting at which they resolved to approach the Crown for an amendment of the Charter in 1826, they did not appear to have taken any pronounced action until the present movement began in consequence of an agitation that had been growing for many years. The President and the Council had for a few years past been in the habit of convening an annual meeting of Members and Fellows, and had placed before them a printed report comprising a record of their transactions during the Collegiate year, and a statement of receipts and expenditure. In the Minutes of the Council the report was officially described as being "submitted" to the meeting. The printed statement included the Council Minutes and other matters of business, and the balance-sheet of income and expenditure for the year. The Council professed to take up the position that they were not concerned in the proceedings of the meeting, and they had generally attended in a separate part of the theatre. They commonly refrained from taking any part in the discussion, but they had not, in fact, insisted upon that view, inasmuch as the president had uniformly taken the chair as of right in his capacity of chairman of the whole community, and the secretary of the College had kept the Minutes as a part of his general duty; and it also happened that a member of the Council had risen to a point of order, while another member spoke and voted in favour of a resolution proposed in the interests of the Members of the College. In addition to that, the Council had received, discussed, and entered upon its Minutes such resolutions as they were directed to do by the general meeting, and had appointed certain of its members as a committee to discuss with the representatives of the Members' Association its policy as to the resolutions passed. With regard to the proposals which had been placed before his lordship for a Charter, the Council, at a meeting on May 5th, 1887, expressly based its refusal to convene a special meeting of the Fellows and Members to discuss the proposed Draft Charter upon the ground that the subjects to which it referred had been already submitted to the Fellows and Members. In view of all those circumstances, it was submitted that the annual meeting recently held was, in fact, a revival of the customary annual mote at which the whole body of Members had always been, and still were, entitled to consider the affairs of their community, and pass resolutions relating to their common interest. The petition on which the present deputation appeared embodied the resolutions passed at the last of those general meetings held on the 3rd inst. The subjects discussed had been under consideration at several previous annual meetings, and gave ample evidence of the steadily growing desire of the Members to obtain recognition of their legal and moral claim to some representation on the governing body. Resolutions tending in a similar direction had been submitted at a former meeting in November, 1886, and were rejected by the Council on Jan. 13th last. With regard to the form in which the present application came before the Privy Council, the deputation desired to say that all the resolutions embodied in the present Members' petition had been duly declared by the Chairman to be carried at the annual meeting, and that a consequential motion was then made and seconded in the usual way that the resolutions be forwarded through the Chairman to the Privy Council. Those were resolutions identical with the provisions of the Charter. That motion the Chairman ruled out of order, and held that the question of forwarding the Members' resolution to the Crown must be left to the decision of the members of the Council. Against that arbitrary action, which affected to abrogate a right permitted even in the dark days of 1797 and 1826, the present deputation on behalf of the Members desired formally to protest. (Hear, hear.) They tendered their present petition to the Crown as being a lawful and constitutional declaration of the Members of the ancient Society of Surgeons in general meeting assembled, and they respectfully prayed the consideration of the Crown to their contention that, especially in such a matter as an application to the Crown for any alteration of the existing Charter, the decision of the whole body of free men ought to prevail against an adverse resolution on the part of the executive. At an earlier general meeting of Members in March, 1884, it was resolved that no alteration in the constitution of the College should be effected without the consent of the Members, and also that there should be an annual meeting. Both those proposals appeared at that time to have received the assent of the Council, and it was submitted therefore that in that respect they had recognised the right of the Members to approve or otherwise the proposals for the alteration of the Charters, and that they ought not

Digitized by Google

now to be permitted to override the constitutional expression of opinion invited on their own action. The Council claimed the right to have submitted to them beforehand any resolutions which were to be submitted to the Members, and to disallow them at pleasure. This claim was not admitted by the Members, and they submitted that it was bad in law. Such cases as had from time to time arisen had been amicably arranged, excepting only on the occasion of the disallowance of a motion to forward resolutions to the Privy Council. The Members submitted that as the President and Council did not exercise the right claimed to forbid the discussion of these proposals, they further admitted the right of the Members to have a voice in the present question. In 1885 the Association of Fellows insisted that no steps should be taken by the Council to obtain a new Charter till the various alterations proposed were accepted by the Council and submitted to the General meeting of Fellows and Members, and that proposal was endorsed by a minority of the Council. He wished to call attention to the fact that the Council in the course of the present year directed voting papers to be issued to all the Fellows, inquiring whether, in their opinion, Members should be allowed to vote in elections for the Council, or whether Members should be eligible for election. The Members objected to the form in which these questions were put. (Hear, hear.) They considered the result, nevertheless, largely in confirmation of the views they now presented. Out of 1116 appearing in the College Calendar only 419 voted. Those were all Fellows who were asked whether their own privileges should be curtailed by the admission of Members, and when it was remembered that the proposal itself to some extent curtailed the privileges of the Fellows, it was submitted that the result was a moral victory. Two hundred and seventy-six answered the official circular in favour of the Members' claim, six sent undecided answers, and 260 returned no reply. About 130 did not appear to have received the circular. About the same time the Association of Members made a private attempt to ascertain the opinion of all the Members of the College, and for this purpose they issued a circular. Taking 10,000 Members as being accessible in this way, of those 10,000 nearly 5000 had signed the petition which had been already placed before the Privy Council in favour of the contention now advanced. That was a clear half, and that was more remarkable because circumstances had proved that the medical profession were slow to return any circulars of that sort. When 20,000 circulars were sent out with regard to the right of voting for the election of members of the General Medical Council, only 5000 were returned; so that if in the present instance 5000 had been returned out of 10,000, that showed a general consensus of opinion, which was very remarkable. With regard to the question of public policy, he would only refer to the objections that had been raised on the part of the Council to the claim of the Members. The first was that the Members never had any right to vote for the governing body; secondly, that the functions of the College were educational and scientific only; thirdly, that in any case the Members were not qualified to take part in elections, and that the extending of the constituency would lead to bad results; fourthly, that analogous bodies did not give to ordinary Members power of voting; fifthly, that any concession of voting power to the Members would be a confiscation of the inherent rights of the present Fellows. Taking the first point, that the Members never had any right, it had been abundantly shown that the election rights of Members were not only undisputed, but were the essential points in the constitution of the Society; and the right of Members to assemble in general meeting for proper purposes had, in truth, never ceased to exist, and was exercised with practical continuity down to the periods of anarchy at the end of the last century, when the Crown overrode the decision of Parliament, and with what was legally known as "fraud" granted the present autocratic Charter. As to the second point, it was notorious that the Members entirely protested against it as a falsification of the real nature of the duties of the College. It was admitted that the business of the College as defined in Section 15 and in the bye-laws was to protect and defend the Members; but it was only quite lately, in the course of the last year or two, and under the strongest pressure, that the Council had shown the least interest or sympathy in defending the Members, and they had done this only in a very small number of cases. Great dissatisfaction existed amongst Members as to the employment of the Wilson bequest—a matter in which they considered they ought to have a voice. The third objection was only an old argument repeatedly brought before select committees and always rejected. Precisely the same argument had been used against the extension of the franchise. With regard to the fourth objection, that there was no analogy in the case of other universities, his lordship was well acquainted with the constitution of the University of London, where the junior graduates had full voting powers and were eligible to be elected on the Senate. In the case of the older universities, it was well known that although it was true the M.A.'s only voted, yet the obtaining of that degree was merely a question of time and the payment of a small fee. The Members were quite willing to submit the limits with regard to age and also as to the number of Members that might be elected on the Council. The next argument of the Council was that there was no case of representation and taxation as alleged, but that the Members paid a fee for their diploma and obtained it, and had no further claim in respect of the money so paid. That argument had been declared by select committees and by Parliament to be out of the question. It was evident that if the payment of a fee gave the Members no right to share in the administration, it was impossible to say why Fellows should have any claims, the rights being the same in the one case as in the other. It should not be forgotten that the Members contributed £16,000 to the funds of the College, and the Fellows only £1000. The exclusion of Members, it was contended, must prejudicially affect the public interest. It was a remarkable fact that in a College numbering from 12,000 to 17,000 Members, including men largely engaged in the Army and Navy and in the Poor-law and Sanitary Services, not one of those services was represented on the Council, or had been for fifty years. The Council of the College, consisting almost exclusively of consulting surgeons, had been, and was still, greatly to its own detriment and greatly to the detriment of the public, altogether out of touch with the great public interests of medicine which had from time to time come before Parliament. The public and the College had suffered greatly from the limitation of its constitution, and by introducing such a representation as was now asked, not only would justice be done to the Members, but the public interest would be very largely advanced.

Mr. TIMOTHY HOLMES said that he represented a very large number of the Fellows of the College who were most earnestly anxious to see the state of things which had been so well described terminated, so that the College of Surgeons should be representative, not only of the consulting Surgeons of London, but also of the whole medical profession engaged in the practice of surgery. (Hear, hear.) He hoped that by the decision of his lordship this end might be secured.

The LORD PRESIDENT said he had, of course, very little to answer upon the present occasion, because it was a matter which he must very carefully discuss, and upon which he must gain as much information as possible upon the various points that had been raised. He was not quite sure that Mr. Hart's view of going back to the ancient guilds would be so very satisfactory to the Members of the body whom he represented as he supposed, because, though he might think upon one point they went with him, upon others they would probably be in a somewhat different category. But, however that might be, he could only say he would give the statements that had been laid before him his most serious and careful attention.

Mr. HART inquired if the Lord President would hear counsel in the event of any legal explanation being required.

The LORD PRESIDENT said that if the Members thought that the Charter was in excess of the powers of the Crown they could raise that point in the ordinary courts of law. No materials were before him for deciding that point. The question before him was the granting of a Supplemental Charter to a Charter which must be taken to be a valid one. If any difficult point arose, he should take care to seek information upon it.

Sir GUYER HUNTER thanked his lordship, and the deputation withdrew.

ASYLUM FOR INCURABLES.—A wealthy Russian lady, named Khvoshtinski, has left £10,000 to found an asylum for incurables in the town of Tamboff.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 19, 1887.

WHATEVER may be the official decision at which the Lord President of the Council may arrive, the reception which he gave on the 11th inst. to a deputation of the Fellows and of the Members of the Royal College of Surgeons of England respectively is not only an immediate gain to the cause of collegiate reform, but marks an epoch in the history of the College. In a second edition of our last week's issue, we published a short account of these deputations, and a fuller report appears in the present number. These reports tell a woful but instructive tale, which may be briefly summed up in the words with which the Lord President dismissed the deputation of Fellows: "It practically comes to this: you want an alteration in the constitution of the Royal College of Surgeons to make it a popular body to a certain extent, instead of being comparatively a close body." This is, in truth, the precise object of an agitation which has persisted more or less, though with dormant intervals, since the first conception of the College in the year 1797—three years before its birth—down to the present time. The principal eruptions of the agitation occurred in the years 1826, 1843, 1848, and 1870. The present outbreak began about five years ago, when an Association of Fellows of that day petitioned the Council to obtain an alteration in the Charter which required compulsory personal voting at the election of members of the Council. At length a committee of the Council was appointed to consider and report on this suggestion and any other alterations that might be desirable in the Charters. At a meeting of the Council held in January, 1884, a list of alterations proposed by the Council to be made in the Charters was presented, and an attempt was made to pass them through the Council and into the office of the Privy Council without the knowledge of the Fellows and Members of the College. Happily this attempt was frustrated, and the proposed alterations were "reported" to a general meeting of Fellows and Members held on March 24th, 1884. At that meeting, at which the proposed alterations had been approved, certain other suggestions were made. These were, chiefly, that Fellows and Members should be invested with a larger share in the management of the College; that there should be an annual meeting of Fellows and Members for the reception and discussion of the report of the Council; and that no alteration should be effected in the constitution or in the relations of the College without the consent of the Fellows and Members convened to discuss such alteration. These demands the Council from the first was unwilling to entertain, and, with the exception of one small concession, has ever since resisted and refused. The immediate effect of this refusal was the creation of two powerful organisations of Fellows and of Members, pledged to uphold the resolutions passed at the general meeting, and to promote in every lawful manner a readjustment of the relations between the Council and the general body of the College. These organisations, known as the Association of Fellows and the Association of Members, soon numbered in the aggregate many thousands of the body politic and corporate. The Association of Fellows confined itself to the principles underlying the proposals made at the general meeting, but the Association of Members, took a bolder flight, and at one swoop attempted to secure an extension of the franchise to all Members, and the conferring on Members rights coequal and coextensive with those of Fellows. It seemed at one time as if the aims and intentions of the two Associations would prove antagonistic and mutually destructive; but by prudent and timely concessions and compromises an *entente cordiale* was established, and for more than two years these organisations have loyally co-operated, each in its own way working for the attainment of the same end.

Both the Associations find a common object in the following approved opinion: First, that it would tend to promote the interests of medical polity and education if Members of the College of ten years' standing were empowered to vote at the election of members of the Council, and if Members of twenty years' standing were eligible to sit in the Council; and, secondly, that no alteration should be made in the constitution or in the relations of the College, or in any of its bye-laws, without the consent of Fellows and Members convened to discuss such alteration. These two propositions have been more than once adopted by large general meetings of Fellows and Members; and at the general meeting held on the 4th inst. a resolution was unanimously passed disapproving of the application for a new Charter which did not contain these provisions. The Council has, however, refused to alter its first decision, and the appeal has now been transferred to the tribunal of the Privy Council. What may be the immediate result of that appeal it would not be right or proper to attempt to forecast. The Lord President has promised to give the matter his best attention, and we must await his decision. What the next stage will be must therefore depend upon that decision; but be this decision what it may, it is certain that henceforth the limits of the controversy will never again be confined to the same narrow area as before. Now that public attention has been called to the defects of the fundamental constitution of the College, it is almost impossible to conceive that the *status quo antea* can much longer be maintained.

CARDIAC auscultation presents ample scope for the scientific exercise of the imagination. The problems that it offers are not to be solved by an appeal to direct experiment; they can only be tested in the light of facts concerning the physiology and physics of the heart and its contents applied to the abnormal conditions of disease, and no position taken up with respect to the mechanism of heart murmurs can be justified, except by appeal to such knowledge. We have been forcibly reminded of this in noting the revival of the controversy around the much-disputed question of the causation of the presystolic murmur, which has been carried on in our columns during the past few weeks, and which culminated in the debate at the Medical Society on the 7th. The same controversy, in which some of the present disputants engaged, raged round the contention of Dr. BARCLAY fifteen years

Digitized by Google

ago. Dr. DICKINSON, in reviving Dr. BARCLAY'S views, has urged them with his characteristic felicity of language and directness of aim. He speaks with confidence of the time when they will become accepted as canons, and is not dismayed at the number and authority of his opponents. It is not the diagnostic value of the bruit that is in question. All admit that it is the typical indication of a stenosed or obstructed mitral orifice; but how and when it is produced—these are the points which have been so strenuously contested, and they are just the points which are so little capable of proof. That wherever the presystolic murmur is noted clinically the existence of mitral thickening or narrowing may be predicated is abundantly proved from post-mortem evidence; but no such evidence can inform us, except only indirectly and inferentially, that the bruit we heard during life was due to the blood flowing in the one direction rather than the other. And, indeed, whilst freely admitting the value of having true conceptions on the mode of production of cardiac bruits, it must be confessed that the all-important fact is the lesion they indicate, and not the precise mode in which they are generated. In this respect the presystolic murmur is pathognomonic.

It may be well—although this is by no means the first time that the subject has been discussed by us[1]—to briefly summarise the arguments that have been raised on the two sides of the question—viz., whether the murmur in question is an obstructive or a regurgitant mitral bruit; whether it be truly or falsely denominated "presystolic." The first place must be given to the attacking party. Dr. DICKINSON based his argument upon several clinical and pathological facts. He avers that, when accurately timed with the apex beat, the bruit and its accompanying thrill are synchronous with that index of the ventricular systole; also that the characteristic loudness and intensity of the murmur are more compatible with its production through the ventricular systole, gathering in force as it proceeds, than with the feeble auricular contraction; that it blends with the systolic sound, and may be continued without a break into an admittedly "systolic" bruit. Its abrupt termination in a "snap" is due to the closure of the thickened cusps after the escape of blood at the beginning of the systole, this closure being delayed by the physical change in the cusps. He would term the bruit preferably an "early systolic," and would discard such phrases as "presystolic" and "auricular-systolic" as misleading and inaccurate. The only direct obstructive murmur generated at the mitral orifice that is recognised by Dr. DICKINSON is the "diastolic mitral" of HOPE, which is comparatively rare. In the correspondence that followed in our columns, these views were supported by Dr. JOHN HARLEY, who declared that he had always regarded the bruit as regurgitant, and who denounced the alternative view as being both "unphysical and unphysiological." Dr. SEYMOUR TAYLOR explained the bruit as being produced by the vibration of the chordæ, and not as generated at the orifice; also that, owing to their altered state, the valves would close more slowly than in health, so that time would be allowed for the murmur and thrill to precede the systolic sound, and yet themselves be strictly systolic. Dr. OWEN TRAVIS showed that normally the valves are uplifted by the blood filling the ventricles, and come together before the actual contraction of the ventricle, but that when diseased they would require a greater force for their approximation, such as could only be supplied by the systole of the ventricle. Dr. CHARLEWOOD TURNER deduced an argument in favour of the regurgitant hypothesis from his observations of a case of pulmonary regurgitation with prediastolic murmur; although he seemed to admit that the presystolic bruit was both direct and regurgitant, and appealed to the cardiograph in his support. Lastly, Dr. HANDFORD argued at length upon the hypothesis that the two ventricles do not act synchronously in mitral stenosis, and that the impulse in this affection is that of the right ventricle, which is probably delayed in its contraction behind the left. All which arguments, it may be noted, have a very considerable theoretical basis.

On the other side, the challenge thrown down by Dr. DICKINSON was taken up by Professor GAIRDNER, who in times past defended his position from the onslaught of Dr. BARCLAY, and who also recently had met Dr. MCVAIL'S physical objections at the Glasgow Medico-Chirurgical Society. As the first clear exponent of the auricular-systolic view, Professor GAIRDNER could not do otherwise than lay stress on the fact that an obstructive mitral bruit may start from the second sound and cover the whole diastole and pause, so as practically to exclude any bruit produced by regurgitation before the systolic sound. The triumphant indication of the value and import of the murmur rendered by his classical and unique case of ball-valve obstruction of the tricuspid was again quoted, for it conveys a lesson which it would be futile to ignore; whilst as to the blending of presystolic and systolic bruits, he averred that this was never so complete as to be capable of discrimination. Dr. GRAHAM STEELL repeated these arguments, and showed that the diastolic mitral had sometimes the characters of the presystolic, with a thrill, in evidence that the auricular contraction can suffice to produce these characters. Dr. SHEARER exposed the fallacy of arguing from the intensity of a bruit to the force of the blood stream, citing in support the character of the *bruit de diable*; he also drew attention to the remarkable curtailment of the period of cardiac rest, which must occur if the regurgitant explanation of the prolonged presystolic murmur be accepted. Dr. G. JOHNSON pointed to the difference in conduction of the presystolic and systolic murmurs, and to the interval that elapses between them, as evidence of their independent origin. He also concurred with Professor GAIRDNER as to the occurrence of combined mitral diastolic and presystolic, and could not explain the abrupt termination of the presystolic bruit on the regurgitant view. Dr. BALFOUR combated the objection as to the inadequacy of the auricle to supply sufficient force to generate a bruit of the character of the presystolic, by pointing to the high tension of the blood in the pulmonary circuit. Dr. SANSOM agrees with the views of Dr. GAIRDNER, but objects to the term "auricular-systolic" as applied to the murmur, and would prefer the word "presystolic." Dr. BROADBENT pointed out that this did not occur in mitral regurgitation where there is the same increase of pulmonary tension. Dr. BALFOUR says he considers the

[1] THE LANCET, 1875, vol. ii., p. 351.

Digitized by Google

duration of the diastolic mitral to be an index of the degree of obstruction; and compares the alleged "continuity" of presystolic and systolic murmurs with that of the double aortic bruit. Dr. SAINSBURY pointed to the post-mortem evidence of auricular hypertrophy, and emphasised the doctrine that loudness of a bruit does not imply force in its production.

The debate at the Medical Society turned almost wholly in favour of the "orthodox" view, if we except, of course, Dr. DICKINSON'S speech, and the indisposition of Dr. SANSOM to accept the auricular-systolic mechanism; for Dr. BRISTOWE, in his elaborate exposition of mitral obstructive murmurs, covered the whole ground, and maintained a position which has not been met by the arguments of the other side. So completely did this paper traverse the question that the subsequent speeches added but little that was fresh, although the Society had the opportunity of examining cases in point. Moreover, it is indisputable that cardiographic tracings, such as those shown by Dr. SANSOM, those of Dr. GALABIN, published in Guy's Hospital Reports (1875), and some which Dr. PAUL CHAPMAN has sent us, support the original notion propounded by Professor GAIRDNER; and as it is only through the cardiograph that we can, independently of the ear, gain knowledge of the actual working of the living heart, we are bound to pay regard to its teachings. In fine, we do not think that the case, ably as it has been presented, has been made out in favour of the regurgitant hypothesis. Perhaps it may be allowed to slumber for another fifteen years, by which time, let us hope, some more certain criteria of the action of the heart in disease will be known.

IT is necessary that the ethics of professional work done "for the good of the public" should be formulated and clearly laid down. The time has arrived when the honour and dignity of the profession demand that a well-considered expression of opinion should be obtained, and by common consent adopted as the guiding rule of practice, to which all will, and in a sense must, henceforward conform, unless, every man doing that which is right in his own eyes, the self-respect of the medical body is to be sacrificed, and the well-being of the many ruthlessly set aside by the impatience or the ambition of the few. The promulgation of hints and suggestions for the management and self-management of the mind and the body in health is one thing, and we have never been backward in this good work ourselves, or failed to appreciate the efforts of others in the same direction—namely, *the prevention of disease and the conservation of health;* but the management and self-management of mind or body *in disease* is wholly another matter, and against the endeavour to popularise this enterprise we have always protested, and must at this juncture enter a strong objection and raise a warning cry. The two endeavours are totally and radically different. The one aims to teach such facts in anatomy or physiology as may be intelligently applied by the non-professional public to the furtherance and preservation of health; the other is a positively mischievous and wholly insincere pretence of enabling and helping laymen and women to do that for themselves and others which it is impossible they should do—namely, treat diseases. We say it is mischievous, because harm must be done by this encouragement of unskilled self-physicking and physicking others. We say it is insincere, because the merest tyro in medicine knows perfectly well that the thing is beyond doing rightly or safely. It would be a dereliction of duty on our part not to speak out plainly on this subject. THE LANCET has done much to popularise the laws of health. Scarcely a week has passed during many years in which we have not issued specially-considered and purposely-written leaderettes or annotations with the express purpose of informing the public, through our medical readers, on subjects of health preservation and the prevention of disease. Nor have we been backward in encouraging this enterprise for the public good whenever and wherever it has been legitimately carried out by qualified members of the profession We are especially desirous to draw a sharp line at the limits of that which is legitimate labour for the public good, and to mark off as obviously incompatible with the honourable practice of our art all that which lies outside and beyond that boundary.

We cannot deem it possible that any intelligent member of the profession can be seriously in doubt as to the impropriety of those enterprises which are now on foot to inaugurate an avowed propaganda of self-physicking in the family. It is monstrous that the semblance of legitimacy should, even for a moment, be given to such a scheme, by the association therewith of names highly honoured amongst us, and borne by persons who have hitherto been regarded as examples of strict and self-respecting conduct in professional life. Do the experience and observation of many long years go for nothing? Have not those who have been brought into contact with the public by service at hospitals, and as lecturers on science applied to public needs, yet learned that "a little knowledge is dangerous" in everything, and in nothing else so much as in the science and art of healing? Do not these gentlemen perceive that by the very sanction of their names in connexion with undertakings which have for their object the teaching of heads of families and the "public" the managing of those about them "in disease," they are giving the lie direct to all they have themselves said and written about the need of a competent knowledge of anatomy and physiology, of pathology, chemistry, and therapeutics, and even considerable clinical experience, before any man can be competent to prescribe? How are persons without any such knowledge to comprehend and apply the hints and suggestions, or even the "broad principles," they propose to cast before them? We cannot excuse the course taken by those who are engaged in this strangely unreal work on the score of want of acquaintance with the facts. It is impossible that persons so well informed as are the partisans of these enterprises can fail to know what they are doing; and if they do know, it follows that they are either pretentiously attempting the impossible or pandering to a false and mischievous desire on the part of the public to make themselves practically independent of medical advice and assistance, and by thus pandering hoodwinking and misleading those they affect to serve. The management of mind and body in health is a matter of common-sense prudence acting on physiological principles, and not only can be, but ought to be, taught to every intelligent being in the land;

Digitized by Google

but the management of the mind and body "in disease" is wholly and specifically a matter for the medical practitioner, and none know better than the physicians and surgeons who stand committed to these novel enterprises that by undertaking to carry out the purpose assigned to them they are breaking roughly and wilfully through rules of conduct framed not one whit less in the interest of the public than of the profession, and which it is unjustifiable to transegress.

What, then, are we to conclude? Frankly, that, carried away by the impulse to achieve popularity or dominated by some mistaken ambition to appear philanthropical, the promoters of these extraordinary schemes of "usefulness" have placed themselves in a position which must be seen to be untenable, and from which they will feel compelled to retreat. We decline to believe that any respectable member of our profession is *consciously* animated by the sordid motive of gain in such a transaction. We do not conceive it possible that it can have occurred to any of those who have committed themselves to the task of teaching the public how to physic themselves and those about them, that the parade of their names and professional qualifications in connexion with these works, coupled with the "advice" they give, is neither more nor less than "touting." Nevertheless, this is what it really comes to. The position taken up is, we say, a false one, and it must be abandoned—the sooner the better—by all honourable professional men. By all means teach the public to take care of their health, show them how to live healthy lives and ward off disease; but in the name of common sense and professional propriety, for the public good, not less than the dignity of the profession, abstain from "quackish" discourses about management in disease. The boundary line between the legitimate sphere of usefulness and that which lies outside and beyond it, and which is not merely useless but harmful, is so clear that it cannot be overlooked or mistaken, except by those who wantonly go astray.

THE passing of green-coloured stools several times a day by infants is dependent, according to M. LESAGE, on the action of certain micro-organisms which he has succeeded in isolating, cultivating, and demonstrating, to his own satisfaction at least, to be the sole pathogenic agents.

M. LESAGE describes two varieties of green diarrhœa. The first is really of biliary origin, for the greenness of the stools is due to biliverdin, and a chemical examination of them demonstrates the presence of bile acids. The reaction of the stools is acid, and this acidity persists even after much dilution, microscopical examination of this variety of green motion having discovered the presence of a large quantity of biliary crystals and cholesterine, and of a certain number of ordinary microbes. The chromogenous bacillus, to be studied hereafter, is entirely absent. This bilious diarrhœa generally appears on the fourth day of life, and ceases by the twentieth or the twenty-fifth. It may supervene in breast-fed or hand-fed infants, is not accompanied by dyspepsia, and does not lead to emaciation. The number of stools is very variable. It appears to be due to an augmentation of the biliary secretion, which lights up a slight enteritis with acid secretion. At a necropsy, twenty-five minutes after death, of such cases, the whole of the intestine contains in its interior much bile of highly acid reaction. Attacks of this form of diarrhœa may be met with also between the ages of two and six months, especially in tuberculous infants.

The second variety of green diarrhœa is very different, for the green colour of the stools is the result of the activity of a special micro-organism. The fæcal matter only contains traces of bile, quite insufficient to explain the special colouration. In athrepsia and in tuberculosis, as the result of steatosis of the liver with consequent acholia, this slight quantity of bile may even be wanting altogether. Chemical examination demonstrates the presence of a special pigment. According to STEINER, in half the cases the stools are neutral; in the remainder the reaction is slightly acid, and mere dilution abolishes even this acidity. At the necropsy, made immediately after death, the intestine is found to be neutral throughout its entire extent if the stools are neutral and the acidity is localised to the colon when the stools are acid, so that the acidity must be developed in the large intestines.

The special micro-organism is a bacillus of varying length, according to the part of the intestine it comes from, to the medium in which it is cultivated, and to its age. The adult form is from 2 μ to 3 μ long and 1 μ broad; it is rectilinear and uniform along all its length; its extremities are slightly rounded. With advancing age it increases much in length, and forms a filament which may be from 5 μ to 20 μ long; it may become sinuous and twisted, or even doubled on itself. It has a certain degree of mobility, less marked than the typhoid bacillus. The bacillus reproduces itself by fission and sporulation: by the former method in the intestine and on potato cultivations; by the latter, outside the organism and on gelatine media, at a temperature of from 20° to 22° C. GRAM'S method is useful for staining this bacillus. The bacillus under different circumstances produces pigment which is not visible in thin layers, but the green colour is very marked in potato cultivations, and lighter in tint on gelatine. A similar variation may be observed in stools. The green tint is heightened by the presence of oxygen; but it has no relation to the bile pigments, for it is not extracted from solutions containing it by alcohol, ether, or chloroform. Saturated solution of sulphate of ammonium may form a solution of the pigment, whose chemistry has not yet been completed. The pigment is not identical with that produced by the micrococcus pyocyaneus. The bacillus may be cultivated in neutral peptonised gelatine, and in serum and agar-agar. Its characteristics are: (1) a green colour of variable tint; (2) the slowness with which it liquefies gelatine; (3) the greenish mantle which forms as the result of the growth of the bacillus on artificial media with a gaseous surrounding. Is this chromogenous bacillus the cause or the effect of the diarrhœa? To this question M. LESAGE gives the answer that the bacillus is the real cause of the diarrhœa, and this conclusion is arrived at as the result of experimental research. The injection subcutaneously of the bacillus gives rise to no lesion or disturbance. The injection of half a Pravaz-syringeful of the pure cultivation into the venous system of a rabbit is followed at the end of ten or twelve hours by the appearance of the pathogenic bacillus and of green diarrhœa. The injection of the bacillus into the intestine (by laparotomy)

Digitized by Google

of young dogs and cats produces the green diarrhœa. The same result ensues if the stomach is the way of entrance, for the gastric juice of a fasting animal only retards the growth, but does not kill the bacillus. The transmission of the bacillus by the atmosphere has been demonstrated by various experiments, according to M. LESAGE. In discussing the treatment of this form of diarrhœa, the reaction of the alimentary canal is first considered. It is not, he maintains, true that the reaction is acid throughout the intestine, even when the mouth and the colon give an acid reaction; the rest of the intestine is neutral. Lactic acid is the best medicament. (See THE LANCET, vol. i. 1887, p. 1149.)

Annotations.

"Ne quid nimis."

SUMMER MORTALITY, 1887.

NOTWITHSTANDING the high temperature that prevailed during July and the greater part of August, it appears from the Registrar-General's last quarterly return that the public health, judged by the recorded death-rate, was below the average during the third or summer quarter of this year. The English annual death-rate during the three months ending September last was 17·6 per 1000, a rate slightly below both the mean rate in the corresponding quarters of the ten years 1877-86 and the rate in the third quarter of last year. The summer death-rate is to a large extent governed by the mortality from infantile diarrhœa, which, in its turn, is mainly dependent upon temperature. The rate of mortality from diarrhœa in the whole of England and Wales during last quarter was equal to 2·1 per 1000, against 1·8, the mean rate in the ten preceding corresponding quarters. As diarrhœa, however, is specially fatal in large urban populations, it will be well to note the mortality from this disease in the twenty-eight large towns dealt with in the Registrar-General's Weekly Return. In these towns the death-rate from diarrhœa last quarter was 3·3 per 1000, against 2·8 in the ten preceding summer quarters, in which the rate ranged from 1·2 in 1879, to 4·2 in 1878 and 4·5 in 1880. The annual death-rate from diarrhœa in the twenty-eight towns, under the influence of the exceptionally high temperature during July, rose steadily from 1·5 in the first week of that month to 5·5 in the first week of August, which was the maximum weekly rate in the quarter. The highest rate in any week of 1886 was 5·7 in the second week of September. The diarrhœa rate last quarter was maintained at 5·3 and 5·0 in the following two weeks of August, after which it rapidly and steadily declined week by week, influenced by the low temperature in September, to 0·9 in the week ending Oct. 1st. The unseasonably cold weather in September undoubtedly spared the lives of several thousands of infants in England and Wales, who would have succumbed to diarrhœa if the average temperature of the month had prevailed. The diarrhœa death-rate in the last four weeks of the quarter, however, averaged but 1·6 per 1000 in the twenty-eight great towns, whereas in the corresponding period of 1886 the rate was as high as 4·6. The diarrhœa rate last quarter, which, as we have seen, was 2·1 in the whole of England and Wales and 3·3 in the twenty-eight largest towns, was 2·2 in fifty other large town districts, and 1·4 in the remainder of England and Wales, exclusive of the seventy-eight great towns. The variations between the diarrhœa rates in different towns were as unaccountably wide as in previous summers; they ranged last quarter in the twenty-eight towns from 0·8 in Halifax, 1·1 in Huddersfield, and 1·6 in Bristol, to 4·7 in Salford, 6·4 in Leicester, and 7·6 in Preston; and in the smaller towns from 0·4 in Southport, 0·6 in Rochdale, and 0·7 in Gloucester, to 5·5 in Chatham and 6·3 in Wigan. The Lancashire towns, as in former summers, showed generally high death-rates from diarrhœa, but some satisfactory elucidation of the causes which produce such variations as 0·6 and 1·7 in Rochdale and Oldham, and 6·3 and 7·6 in Wigan and Preston, is still urgently needed in the best interests of sanitary progress.

SIR HENRY ACLAND ON THE ARMY MEDICAL SCHOOL.

SIR HENRY ACLAND has done well to allow his Address to the Army Medical School, delivered in July at the distribution of prizes, to be published. It might be thought that one of less eloquence and authority than Sir Henry Acland might have sufficed to vindicate the claims to continued existence and increased support of the Netley School. But it is not so. The scandalous calamities of the Crimea are now far enough off to be forgotten by eager politicians who think they can make a little party capital out of any proposal of paltry economy, which may not bear disastrous fruit till their petty purposes are served. But they are not forgotten by the nation, and will not be suffered to recur for want of the few thousands a year that the Netley School costs. This is not the time when we can afford to relax the cultivation of military hygiene and medicine. Our army and navy are too small, and the duties and the distances to which they are called are too great, to allow any such experiment. If anyone is in doubt on this subject, let him read the stirring words of Sir Henry Acland, in which he relates the origin of Netley School in the sufferings of our Crimean troops—"sufferings..... in which sickness destroyed far more than were slain by the sword or the projectile, and which were such as to shock the most thoughtless." The very triumphs of medicine and hygiene tend to make nations forget what will happen if they fail to cultivate these sciences, especially as affecting the services on which our safety depends. But Sir Henry spoke not only to public men who on superficial financial grounds would starve or abolish such a school as Netley, but to the students and candidates of the school, and gave them much good advice. Few men were more fitted or entitled to give it, or to commend to them the great lessons and the great teachers of recent years in respect of army medical organisation, and to inspire them with lofty thoughts in repairing to the distant dependencies of the Empire on their beneficent mission.

HUMAN LOCOMOTION.

M. MAREY, whose brilliant researches into the *kinematics* of animal movements are so well known, has, in collaboration with M. Demeny, been making a series of observations upon human locomotion, of which a highly interesting account appears in a recent number of the *Comptes Rendus* of the Académie des Sciences. The method employed has been that of "photo-chronography," and the experiment is described as follows:—"In order to obtain a representation of the movements of torsion about a vertical axis, we covered a floor with black velvet, and caused the subject of the experiment, attired in white, to pass beneath a photo-chronograph placed vertically at a height of about 40 ft." In this way the investigators obtained a series of successive images, from which they publish a selection, displaying movements complementary to those movements in the vertical plane which have been photographically registered some time ago. In order to obtain more exact materials for measurement, they clothed their subject in black, and fitted to his shoulders and hips white wands, marking the transverse horizontal axes at these points. Of the index lines so depicted they obtained a series of photo-

Digitized by Google

graphic drawings at intervals of one fiftieth of a second. These, when viewed from above, afford of course a measure of the torsion of the trunk about a vertical axis; viewed horizontally, they exhibit the torsion about the antero-posterior axis. A third white wand attached along the spine and projecting above the head affords indications of the "movements of totality"—that is to say, of balancing movements by which the whole body is inclined forward or backward or to either side. The joint authors give a minute analysis of the results which they bring out, and a careful description of the torsions to which the body is subject in walking and running, and their most interesting result is an approximate proof that at a walking pace the movement of the head is by compensatory motions in the trunk reduced to a minimum, and assimilated closely to that of the centre of gravity of the whole body. This they prove by means of an ingeniously constructed diagram, in which the trajectories of head, shoulder, and hip are brought together for comparison. It then appears that the trajectory of the head lies always midway between those of the shoulder and hip, so that the middle point of a line joining hip and shoulder would have a motion almost identical with that of the top of the head. There still remains, however, the antero-posterior swaying of the body to be allowed for, but this in walking amounts to very little more than zero. A further investigation of this interesting relation is, however, promised in M. Demeny's name, and will doubtless well repay the attention that is being bestowed upon it.

SMALL-POX HOSPITALS.

A CASE of some importance to sanitary authorities came before Mr. Justice Stirling, in the High Court of Justice, on Tuesday. The guardians of the Wortley Union, a district adjoining the borough of Sheffield, had hired for use as a small-pox hospital a house abutting on a road leading to three other houses, which were situated at a distance of less than fifty yards from the hospital. Application was made by these inhabitants for an injunction to restrain the guardians from the use of the house in question as a small-pox hospital. On the first hearing Mr. Justice Stirling expressed the opinion that the case was a proper one for an independent inquiry by a person skilled in such matters, and he accordingly appointed Mr. Shirley Murphy to inquire and report to him as to whether, by reason of the situation or management of the institution or otherwise, there was any danger to the plaintiffs, or any of them, in its being used as a small-pox hospital. After inspection of the locality, Mr. Murphy reported that there was danger, but the danger was slight, amounting rather to a possibility than to a probability of infection arising from the hospital. His lordship, in giving judgment, said that the position of the law was clear; the burden of proving that the use of this building was a nuisance lay upon the plaintiffs, and the question was whether the amount of injury was sufficient to justify the Court in treating this as a nuisance to be restrained by interlocutory injunction, and, in the words of Lord Justice Cotton, in the case of Fleet *v.* the Metropolitan Asylums Board, there must be "an appreciable injury to the healthiness of the plaintiffs' property. The plaintiffs must make out that there was real danger, otherwise, however much they might feel the hospital to be an annoyance, they could not get an injunction. In the present case it was true that the amount of the danger was not very great, but, on the other hand, it was a case in which from the particular nature of the disease its damage might be of an irreparable character." He therefore granted the injunction. We may comment on the wisdom of the course adopted by the learned Judge in obtaining independent skilled assistance for the purpose of enabling him to arrive at a conclusion—a far preferable method to that of merely hearing the often conflicting evidence of witnesses.

THE PARKES MUSEUM.

WE are sorry to see that this excellent institution is in want of funds, and that unless assistance is forthcoming its career must close. A powerful appeal has been made to the public and the profession by the members of council, and we feel sure that our readers will not allow these gentlemen to appeal in vain, more especially as they themselves have given very solid proof of the disinterested earnestness with which they heretofore have supported the museum. Eleven years ago the museum was only an idea; now there is a building, a very extensive collection of sanitary apparatus, and a large and valuable library, which is daily growing. The total cost of supporting the museum and library is, we believe, something under £700 a year, and it is still impossible to think that this modest sum will not be forthcoming. It is pointed out that the museum is a purely educational museum; and certainly the lessons to be learnt in it are of the utmost importance to the medical profession, who cannot afford in the present day to be ignorant of the details by which we seek to secure health in our dwellings and elsewhere. The professors and teachers of hygiene at all the chief medical schools bring their pupils there for practical instruction, and were the museum to be abolished our medical schools would feel the want of it. It has been used also for examination purposes, and we should hope that the great examining corporations will see their way to making a grant for the support of an institution which is of real importance for the practical teaching of medical students. Those who become members or life members will not only be helping the museum to continue its career of usefulness, but, as appears by the winter programme just issued, they will have their money's worth. Eleven lectures are to be given during the winter and spring, and of these the first was given by the Earl of Meath on Thursday last. Sir Douglas Galton will lecture on Smoke and Fog on Dec. 1st, and Mr. Shirley Murphy on Scarlet Fever on Dec. 15th. The first lecture in 1888 will be on Jan. 5th, on Hygiene in Childhood, by Dr. Angel Money, and on Feb. 2nd, Professor Crookshank will take for his subject the History and Present Position of the Germ Theory of Disease. Dr. Payne, whose antiquarian lore is well known, will discourse on Plagues Ancient and Modern, on Feb. 16th; and he will be followed at intervals of a week or a fortnight by Dr. Sims Woodhead on Milk and Disease, Miss Chreiman on Physical Culture, Mr. A. S. Murray on the Physical Training of the Greeks and Romans, Mr. Justice Cunningham on the Public Health in India, and Professor Hayter Lewis on Ancient and Mediæval Towns. Membership and life membership give admission to the lectures, and also the free use of the museum and library, and we trust that many of our readers who have not already done so will come forward, and by participating in the advantages of the museum help to secure its benefits for others.

THE MEDICAL FACULTY OF LYONS.

THE Medical Faculty of Lyons, which has just completed its first ten years of existence, has great reason to be proud of the success which has attended its formation. It now boasts of nearly 800 students, and is therefore one of the largest medical schools in Europe. But it is not only of numbers that it has cause to be proud. Although its *alumni* are necessarily as yet but very young men, they have successfully asserted their superior ability in several of the *concours*, or public competitive trials for professorships, lectureships, prizes, &c. The Lyons Faculty is now able not merely to provide all its own junior teachers for itself, but it has given teachers to other Faculties. Thus, up to the present time Lyons students have gained five professorships; besides, fifteen are *agrégés* or

Digitized by Google

assistant professors. Perhaps the greatest compliment which the Lyons Faculty has received was when Paris took Professor Chauveau to be Professor of Physiology. There has always been a tendency for the Paris Faculty to overshadow the French provincial Faculties far too completely for its own good; therefore the exhibition of the healthy rivalry of one or more of the provincial schools is much to be rejoiced at, even for the sake of the great metropolitan Faculty itself. If Lyons, Montpellier, and Bordeaux held the same relationship to Paris that Leipsig, Munich, and Bonn hold to Berlin, it would be far better for the cause of medical science in France.

RABIES.

THE method of discussing any subject by the use o questions is generally suggestive and almost always instructive. The interrogative method has been adopted by M. Duboué in his pamphlet entitled "Des Progrès accomplis sur la question de la Rage,"[1] which discusses the part played by the nervous system. We reproduce the questions asked and answered in some measure by M. Duboué, who is a firm supporter of Pasteur. Is the virus of rabies propagated from the bitten part towards the medulla by the agency of the nerves? Granted that the virus is transmitted during the period of incubation by the nerves, and in a centripetal direction, may we conclude also that its transmission is effected equally in an opposite, centrifugal direction? Further, is the virus propagated through the agency of the sensory or of the motor nerves, or do both kinds of nerve convey the poison? Is the duration of the period of incubation to be explained on the distance between the bitten or inoculated part and the spinal bulb? What influences are exercised by age and mode of alimentation of the inoculated animals and by the rectilinear or angular direction of the contaminated nerves on the duration of incubation? When once the virus has reached the bulb in a centripetal manner, is it then reflected along other nerves in a centrifugal fashion? If the answer be in the affirmative, which can only be ascertained by experiment, which are the affected nerves? Does the poison pass across from one side of the cerebro-spinal axis to another, or does it remain limited to the side first affected? At what exact moment of time does the saliva become virulent? Does this occur only during the period of incubation, or only during and after the period of invasion? Are other liquids than the saliva infective—as, for example, the bronchial mucus and those liquids which come in contact with the contaminated nerves? Perfectly satisfactory answers to these questions would certainly advance our knowledge considerably, and the knowledge attained would hereafter prove of value in the rational treatment of this fell disease.

SMALL-POX IN MILAN.

AN Italian correspondent writes:—"The small-pox epidemic now prevailing in the Lombard capital is of serious import for the English-speaking traveller, who, if he seldom resides for any considerable time there, is in the habit of making it a half-way house, to the number of many thousands every season. As in Florence, so in Milan the disease has declared itself among the non-vaccinated, and, to a smaller extent, among those imperfectly vaccinated. To the former category belong the infant victims; to the latter the adults, many of whom have reached ages averaging from sixty to seventy years. This outbreak, as the Milanese journals indicate, is another warning to the Italian Government to lose no time in enforcing a universal system of compulsory vaccination throughout the peninsula, and in putting an end, once for all, to the inadequate precaution which contents itself with making admission to school, to the army, or to the civil service conditional on the applicants having been vaccinated. Meanwhile the Town Council is offering every facility for primary or secondary vaccination—all classes, both in city and suburb, being freely invited to avail themselves of the prophylactic gratuitously afforded in the Piazzale delle Galline. As an additional inducement to have the operation performed or re-performed, the authorities announce that the supply of lymph has been greatly improved in quality. The trials made of this fresh supply by Professor Grassi have answered all expectations, and the Vaccination Committee congratulate themselves on having now for the sixteenth time, during their nineteen years' experience, so ensured the efficacy of the prophylactic that nothing but its compulsory enforcement is wanting to make small-pox as rare in Italy as it has long been in England, France, or Germany.'

[1] Paris: G. Masson, Boulevard St. Germain.

THEORIES OF HOSPITAL REFORM.

OUR contemporary, *Charity*, gives an account of an essay on Hospital Reform, by Mr. Richard Moreland, honorary secretary of the Finsbury Dispensary. Mr. Moreland's views seem somewhat peculiar. According to one of these, much of the financial depression of hospitals is due to "the fact that committees, medical staffs, and nurses do not in many cases act sufficiently in concert." More seriously still, he attributes much of the want of harmony to the medical staff, who, according to the representation of his views in our contemporary, "are continually at loggerheads," because each one wants to have the patients treated according to his own peculiar theory. The nurses catch the contagion of this discord, and the time of the committee is spent in adjusting quarrels which should be spent in more profitable and creditable work. We cannot but think that this is rather a far-fetched theory of hospital difficulties, and, so far as regards the medical staffs, essentially an inaccurate one. We are glad to see that, in spite of the blame he attaches to the medical staff, Mr. Moreland is, somewhat inconsistently, disposed to give them more active interest in the regulations of their hospital. Mr. Moreland would approve of patients contributing to their maintenance; and of nurses, sisters, students, and probationers paying special fees. He would have one or more wards in each institution constantly closed, and so reduce expenses and permit of cleansing. Further, he advocates the merging of smaller hospitals into larger ones, with a view to reducing expenses of separate maintenance. Some of these views are highly worthy of consideration, others are more doubtful; but none of them go to the bottom of the financial difficulties of hospitals, which are to be found in an imperfect conception of the suffering they are calculated to relieve. When this is once realised, the wealthy will pour their money into the treasury of hospitals.

THE WATER-SUPPLY OF BADSEY.

THE inhabitants of Badsey in the Evesham rural district are a people easily contented as regards their water-supply. They have evidently no knowledge of Sir John Simon's writings; otherwise, instead of talking about a low death-rate in connexion with the state of their existing wells, they would bear in mind what he said as to arrears of impunity in the matter of neglected filth being often cancelled in one dreadful blow. But they have even endorsed a resolution to the effect that their water is, except in a few cases, too good to be set aside for another. In one instance a grave was being dug in Badsey, but it commenced to fill with water, and during the time occupied in conveying the coffin from the church the grave became flooded. The result was that the water had to be baled out, but it

Digitized by Google

was found that this operation had almost dried a well supplying two houses. After rain, some of the water becomes the colour of porter, but this does not suffice to condemn it in the minds of the villagers. They are apparently scientifically inclined, and they prefer basing their final judgment on the result of a quantitative examination of the water such as chemists usually supply, to forming any estimate on such trivialities as obvious churchyard soakage and porter-like colour. We believe the Local Government Board have the question in hand, and it is possible that, in view of such evidence of contamination as is forthcoming, they may not be so particular as to the chemical constituents of the filth that soaks into these wells.

AN ARTIFICIAL ATMOSPHERE FOR PHTHISIS.

DOUBTLESS a perfect atmosphere for cases of chest disease, and especially phthisis, must remain for a long period a utopian idea. The subject of an artificial atmosphere was raised recently at the Biological Society of Paris by M. d'Arsonval, who described several apparatus constructed by him for permitting patients, and especially phthisical ones, to respire an artificial atmosphere, and he showed a means by which the inspired air should be uncontaminated by the fluid in the expired air. Dr. Brown-Séquard, in the discussion thereon, said it would be very important to settle this point in the hygienic treatment of *poitrinaires* and others. He had tried to employ an atmosphere containing a rather larger percentage of oxygen than the normal of ordinary air; but he found that when the oxygen was in too great a quantity irritation resulted, causing considerable distress, even when the carbonic acid eliminated remained normal. If, nevertheless, a mixture in determined proportions of carbonic acid and oxygen be made in an artificial atmosphere, these phenomena of intolerance were no longer produced. It is known that carbonic acid, besides its anæsthetic property, exercises a cicatrising effect on wounds. It is possible to comprehend how, in cases of tuberculosis, a diminution of reflex sensibility, and consequently a lessening of cough, may be afforded, whilst at the same time the pulmonary lesions may be favourably influenced, by carbonic acid.

PUERPERAL PEPTONURIA.

PEPTONURIA accompanies every normal accouchement, but it does not always present identical characters, and certain causes may modify its intensity and its duration. According to M. Barone, it is but little marked on the first day of the puerperium, but augments on the second and the third, attaining its maximum on the fourth. From this point it gradually decreases, undergoes a manifest augmentation towards the eighth or ninth day, and then again lessens until the twelfth, when it disappears. This peptonuria is explained as a collateral phenomenon of the involution of the uterus, and it is not necessary to suppose that a purulent exudation is concerned in its causation. It has been remarked that if the fœtus is macerated, peptone is not found in the urine, or only in small quantity; the diminution is in direct relation with the time that elapses between the death of the fœtus and its expulsion from the womb. It appears, then, that involution may be more rapid than when the child was born alive. Urine passed on the last days of gestation also contains peptones, which may also be found during parturition. Peptonuria has no relation with the kind of uterine contractions, nor with a painful or prolonged parturition. Uterine involution follows the same course as the peptonuria; the two conditions vary concomitantly; when the uterus has sunk to the level of the symphysis pubis peptone is no longer found in the urine. The specific gravity of the urine augments in direct parallelism with the increase in the peptones. M. Barone concludes that the peptones formed in the uterine parenchyma behave themselves in regard to the blood precisely as do the peptones of digestion, and as do also the peptones artificially injected into the blood.

THE ANTI-VACCINATIONISTS AND THE LORD MAYOR.

THE Lord Mayor has begun well. Being asked to allow the use of the Mansion House for a public meeting on the question of compulsory vaccination, his lordship sent the following answer through his secretary:—

"The Mansion House, London, E.C., Nov. 12th, 1887.

"DEAR SIR,—I am directed by the Lord Mayor to say not only that he must decline the request of your committee to grant the use of the Mansion House for their meeting, but that he is most thoroughly opposed to their sentimental antagonism to a recognised, wise, and humane law.

"I am, Sir, yours very truly, W. J. SOULSBY."

The trumpet of public men is apt in these days to give an uncertain sound on life and death questions. The morbid desire to please is a public evil. The Lord Mayor might as well be asked to allow a meeting at the Mansion House to discuss the expediency of fire brigades. His decision is refreshing, and will enhance public respect for the Mansion House.

HONOURS IN BRUSSELS AND IN PRUSSIA.

AT the recent third examination for the degree of Doctor of Medicine in the University of Brussels 10 candidates were successful, all but one of them obtaining more or less "distinction"; thus 2 obtained "the highest distinction," 3 "great distinction," and 4 "distinction." It is instructive to compare this list, which is of the usual character for Brussels, with the statistics issued by the examining commissions of the ten Prussian universities charged with applying the test, not for medical degrees, but for the mere licence to practise. During the examination year 1886-1887 694 candidates, many of them already Doctors of Medicine, were examined. Of these 505 passed, 270 obtaining the mark "good," but only 20 the mark "very good." The University of Berlin sent the largest number of candidates (232), that of Marburg the smallest (35). The Pharmaceutical Commission reports that 270 candidates were examined, of whom 218 passed.

THE LANGUAGE OF PRESCRIPTIONS.

THERE is among medical practitioners an increasing disposition to substitute for the series of classical terms hitherto usual in prescribing, their simpler and more accurate equivalents in the vernacular. The reform is one which has our approval. In making this admission, however, it is necessary to define with some preciseness the extent of its application. For the purpose of the present argument a prescription may be conveniently regarded as consisting of a professional and a popular part, the former being concerned with a statement of drugs and their quantities, the latter with directions for their use. The first great requisite that should belong to such directions is, we take it, clearness. Their meaning must be plain beyond all chance of misunderstanding on the part of inexperienced dispensers, a result hardly to be expected if words, phrases, and abbreviations are clothed in a garb of studiously quaint antiquity. The advantage conferred by a common scientific language is in this connexion, as a rule, wholly inoperative, since a translation of injunctions to the patient is not usually required, and, should it be needed in consequence of a change in the medical attendance, is not difficult to obtain. Doctor, chemist, nurse, and patient are here on common ground that has less to do with medicine than with attendance on

Digitized by Google

the sick, and their simplest and surest means of communication is the native tongue. It is otherwise when we come to component parts and quantities of a prescribed mixture. These are the special concern of practitioners, and a clear and easy understanding among all such, of whatever country, with regard to the means of treatment, is of the first importance. Alike for this purpose and to allow of advisable brevity, the use of one common medium of expression is decidedly preferable to any other system. We are therefore of opinion that the best and most natural result of the reform in prescribing which is now in progress will be to leave the body of the prescription in its present convenient though antique form, and to ensure the most accurate observance of instructions to the patient by expressing these in the language of every-day life.

DIPHTHERIA AT SHIRLEY.

SOME of the principal inhabitants of Shirley, which lies within the borough of Croydon, have, after exhausting every other attempt to secure a remedy, appealed to the public press in order to expose an alleged default of the Corporation to deal with a condition of nuisance which is locally believed to have been the cause of diphtheria. The place, it is stated, has been provided with sewers and sewer ventilators, and by means of these latter the air of the place is contaminated, and fatal and preventable disease is induced. Failing to get any local redress, the complainants last January laid their case before the Local Government Board, who, after an incomprehensible delay, suddenly sent down an inspector, who arrived without notice, and failed to see many of the principal persons concerned. A recommendation was then made to the effect that pipe ventilators be provided for the sewers; but after six months' interval nothing whatever has been done, and both diphtheria and scarlet fever are alleged to be still in the place. Few things are more difficult than to eliminate all sources of error due to personal communication at school and in other places, and to state decisively that diphtheria has been due to sewer emanations. But it is equally certain that unless some other cause can be assigned without risk of error, it is nothing less than culpable to leave such obvious conditions of nuisance untouched, and this for nearly a twelvemonth after the first cause of complaint arose. The Croydon Town Council seem about equally divided as to the question of nuisance from the street ventilating shafts, and between the two opposite parties Shirley is allowed to remain without a remedy. We observe that, in a letter to *The Times* of the 17th inst., the chairman and vice-chairman of the Sanitary Committee of the Croydon Town Council aver that "the general health of Shirley is exceedingly good," and that the sewers of the district are not more offensive than those of places where the population is sparse and the quantity of liquid flowing down the sewers is comparatively small.

UNDERSELLING PRACTITIONERS.

IT is lamentable to think that the feelings, if not the circumstances, of medical men in some places have sunk so low that they underbid for appointments. A provincial newspaper contains reports of two instances. We fondly hope that there is some inaccuracy in the statement. In one case there was keen competition between two medical men. When one was appointed club doctor, it was decided that he should receive 3*s.* per annum per member—i.e., 2*s.* a year less than should be paid to club surgeons. But "last week," says our contemporary, "an offer was made to do the work at a cheaper rate—viz., 2*s.*!" In the other instance, the services of a gentleman as medical officer of health were required by the Local Board. The appointment was advertised at a salary of £20 a year. The feeling in favour of the resident gentleman was well known. But a tempting offer was sent in to take the duties for £6! To the credit of the Local Board, they resisted this temptation. We are glad that the names of the places and the persons are not given. But, speaking impersonally, we cannot too strongly express our surprise and regret that any medical man can be found so little alive to the dignity of his profession and the value of his own services as to offer the latter on terms lower than those offered, and for appointments already held by another medical practitioner. Very little different is the conduct of the new practitioner in a district who, by lowering fees to catch patients who can pay higher fees, brings himself and his profession at once into disrespect. Our contemporary says that if this competition among doctors could be extended, doctors' bills would be substantially less. Perhaps so. It does not follow that justice would be done to a liberal profession, or that, in the long run, the public would be better served.

FEVER IN LONDON.

THE trifling decline in the prevalence of scarlet fever, on which we commented in our last issue, has become more pronounced, and during the week ending November 11th 228 cases of this disease were admitted into the Metropolitan Asylums Board hospitals, the number during the preceding week being 265. Scarlet fever is therefore behaving during the present year much as it has done in past years, and we may reckon on the decline being maintained during November and emphasised during December. Already the admissions during the present week have shown that the fall is not merely temporary. Of other diseases, twenty-seven fresh cases of enteric fever were admitted into these hospitals during last week, and one case of small-pox was received, the patient previously living in the parish of St. George-in-the-East. Two patients not suffering from infectious fever were also removed to the hospitals.

FIRES IN HOSPITALS.

PUBLIC attention has recently been directed to the especial horrors which must attend an outburst of fire in a hospital. The terrors of fire breaking out among a bedridden population cannot be over-painted, and it certainly is the duty of the governors of the great medical charities to see that all reasonable precautions are taken for dealing with an outbreak of fire. We have reason to know that in some of our hospitals considerable expense has been incurred in providing buckets, hose, water cocks, fire cisterns, and printed regulations, which are displayed throughout the building. It is difficult to see what more can be done, except in construction with fireproof materials; but as most of the hospitals have not funds enough to adequately pay their way, it seems futile to tell the managing bodies to rebuild. The risk of fire in hospitals is not so great as it is in some other buildings: first, because none of the work carried on in a hospital involves any special danger in this respect; and secondly, because, as a rule, there are nurses and attendants on the alert in nearly every part of the building at all hours of the day and night, and it is not likely that a fire could make much headway without discovery. Nevertheless the danger is undeniable, and it is well to draw attention to it now that winter is fairly with us. There is always some extra risk during the "Christmas entertainments" which it is now the fashion to give annually in many of our hospitals. Most of these entertainments involve extra lights, the transport of lamps, and not unfrequently the illumination of combustible Christmas trees; and it has always been a question with us whether, considering the undoubted risk which they involve, these entertainments

Digitized by Google

should be permitted in the main building of a hospital. We have no wish to deprive those who unfortunately spend Christmas in hospital of such comfort and happiness as the season may bring, but we feel bound to say that, unless such entertainments can be given without risk, the authorities who have control of the hospitals would do well to limit the Christmas bounty to the distribution of gifts &c. In the construction of a hospital, escape in case of fire should ever be present to the architect's mind. The main thing seems to us to be the provision of sufficient staircases, so that from all parts of the building the patients may have a choice of staircases, which, of course, must be wide enough to allow a bedridden person to be carried down. Many of our hospitals are somewhat antiquated in design, and might doubtless be improved by rebuilding, but that is a matter which rests with the public, from whom the necessary funds must come. The governing bodies cannot be blamed if, without funds for building, they have to make the best of possibly imperfect edifices.

BIRMINGHAM AS THE SEAT OF A UNIVERSITY.

FOLLOWING an elaborate paper by the Rev. Dr. Crosskey at the Philosophical Society, and a discussion on the same introduced by Professor Haycraft, a paper was read by Mr. James Heath, M.A., at the University Graduates' Club, on the 15th inst. The medical element in the scheme is an important one, and closely affects the existing institutions of the Queen's and Mason Colleges. It is to be hoped that the subject will be pursued, and that, if it is to be carried out, some means will be adopted to remove the greater objections, which appear to be mainly of a financial kind. The formation of a degree-giving body should not be the only aim—already numbers of these are present—but the consolidation of existing institutions for the purposes of higher educational requirements, technical and otherwise.

A SCARLATINA CURVE.

IN his last number of the Sanitary Chronicles for Marylebone, Mr. Wynter Blyth gives a diagram based on the statistics of the past thirty years for England and Wales, showing how scarlatina is influenced by season. The deaths are shown to be at their lowest ebb at the end of February and the beginning of March; after this they rise, the increase being rapid during May and June, and then more gradual up to the middle of October, when a steady fall commences. The fall increases rapidly in December; it is sudden during January, and continues until the minimum fatality is again reached soon after the close of February. Every epidemic does not necessarily follow this course; but there are grounds for assuming that our metropolitan prevalence will, in all probability, be governed by much the same influences as those which are indicated in the curve referred to.

GLASSBLOWERS' SYPHILIS.

PROFESSOR E. DE SMET of Brussels, in lecturing on a case of syphilis occurring in the mouth of a glassblower, referred to several epidemics which have been reported as having occurred amongst artisans of this description, and remarked that only two plans for preventing these outbreaks had been devised—viz., giving a separate movable mouthpiece to each man and instituting frequent rigorous periodical inspections of the persons of the *employés*. The first plan is always declared by the workmen to be impracticable from the loss of time which it would occasion by fitting the different mouthpieces on the tubes. The second would of course be resisted by the men, but he thinks their objections could be overcome by showing them the danger to themselves and their families of the present system.

THE HEALTH OF THE CROWN PRINCE.

IN another column will be found an article by Sir Morell Mackenzie on the case of his Imperial Highness the Crown Prince of Germany from the time of his visit to England till his arrival at San Remo. In the report, which is published by the wish of the illustrious sufferer, Sir Morell briefly recapitulates the salient points in the Prince's illness, and states that the extension of the fresh growth since it was first seen has always been upwards. During the last visit of the English laryngologist to San Remo a complete view of the new formation at the lower part of the larynx was for some days rendered impossible by the intense œdema of the mucous membrane, which, in Sir Morell's opinion, was due to limited perichondritis, probably set up by the growths which have been formed from time to time in the larynx. It is the opinion of Sir Morell Mackenzie that, although the nature of the growth which has lately appeared has not been determined by microscopic examination, it presents every appearance of cancer.

THE OBSTETRICAL SOCIETY.

ON Wednesday next, the 23rd, the meeting of this Society will be devoted to the discussion of the subject of Extra-uterine Gestation. Papers will be read by Dr. Herman, Dr. Champneys, and Dr. John Williams. By an error this meeting was put down in our diary last week for the 16th.

STATESMAN AND OPERATING SURGEON.

DR. ZALDIVAR, formerly President of a South American Republic, is now on a visit to Spain. Though considerably occupied with political matters, he finds time to pay attention to those connected with his original profession—that of medicine. Having specially devoted his attention to ophthalmic surgery, he was invited by Dr. Osio to operate in his clinic. The ex-president performed an iridectomy and operations for cataract, pterygium, and several other affections of the eye, in the presence of many of the heads of the profession in Madrid. All were afterwards entertained at a brilliant luncheon by Dr. Osio.

RELATIONS OF HOSPITALS AND DISPENSARIES.

WE direct the special attention of our readers to the Conference to be held on Nov. 22nd, at the Society of Arts, 18, John-street, Adelphi, to discuss recommendations framed by the Medical Attendance Organisation Committee. Sir Spencer Wells will preside. All interested in hospitals and dispensaries and the difficult questions connected with medical attendance on the wage-earning classes should attend.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Ignaz Havas, formerly Dean of the Medical Faculty of Buda-Pesth, at the age of eighty-five.—Dr. Mering, Professor of Special Pathology in Kieff.

A JUST JUDGE ON PATENT MEDICINES.

MR. JUSTICE KAY, in the Chancery Division, in the case of C. A. Vogeler and Co. *v.* Middleton, was asked to restrain the defendants from advertising and selling an oil as St. Joseph's Oil, as being an infringement of the plaintiff's trade mark, and calculated to deceive the public. Mr. Justice Kay said that both the plaintiffs and defendants were vendors of quack medicines which were largely advertised to heal all manner of external injuries. He declined to rule that the

Digitized by Google

use of any saint's name in the calendar was an infringement of the plaintiff's trade mark. But lest either party should use his judgment as an advertisement, he hoped they would add that no one should employ either preparation except under medical advice. The judge's counsel is excellent. It is too much to expect that the parties to the suit will publish it. But we gladly give it publicity and praise.

CHOLERA NEWS.

ACCORDING to a telegraphic communication, a few cases of cholera still occur at Messina. Malta is now stated to be entirely free from the disease; and clean bills of health have been issued. If this is strictly correct, the final disappearance of the disease from the island must have been rather sudden. On the other hand, the South American continent, which is in such free communication with Italy for purposes of emigration, is again attacked, cholera having appeared in Santiago. Last winter the disease prevailed widely in and about this and other Chilian ports.

WARWICK JOINT BOARD HOSPITAL.

WE are glad to record that, after many difficulties and delays, the Warwick, Leamington, and other sanitary authorities included within the area of the Warwick Union have at last laid the foundation stone of their new hospital for infectious diseases. The hospital is conveniently situated for the more populous localities needing it; and, since it is being erected from the designs of Mr. Keith D. Young, who has had such exceptional experience as regards these buildings, there can be but little doubt that it will be well adapted to the requirements of the district.

FOREIGN UNIVERSITY INTELLIGENCE.

Bordeaux.—The session which is just commencing has already seen the inauguration of the new buildings, amongst which the Anatomical Institute is especially worthy of note; indeed, it has been enthusiastically declared to be the "first anatomical institute in the world."

Buda-Pesth.—Professor Wagner having resigned the chair of Medicine, the post is advertised as open to competition. The stipend is 2500 gulden with a lodging allowance of 400 gulden, a total of less than £300 per annum.

Helsingfors.—This Russian university being in Finland is under different regulations from the others. The language in which instruction is given is neither Russian nor Finnish, but Swedish, so that the scientific work which emanates from Helsingfors finds its way into Scandinavian rather than into Russian medical journals. There are at present 974 students, including 8 women, in the university. Of these only 77 belong to the medical faculty.

Lille.—The Faculties of Law and Arts of Douai are to be moved to Lille, which will then have no less than nine faculties, a unique position for a French manufacturing town. The townspeople, however, are welcoming what may be looked upon as the growing up of a northern university amongst them, and are subscribing a large sum, amounting to something like £100,000, for the erection of the necessary buildings.

Madrid.—Don Francisco Criado y Aguilar, Professor, first of Hygiene and subsequently of Obstetrics, in Saragossa, has been appointed Professor of the Diseases of Children. Don Francisco de Certajarena, Assistant Professor of Surgery, has resigned his post.

Montpellier.—Bitter complaints are being made that the wishes of the Faculty concerning some questions connected with the appointment of professors have been disregarded by the Government. A desire is being expressed here, as well as in other provincial medical schools, that each Faculty should be allowed a much larger degree of autonomy without the vexatious centralisation which now exists.

Naples.—Dr. G. Nicolucci has been promoted to the Professorship of Anthropology.

Pisa.—Dr. Griffini has been appointed Professor of General Pathology.

Rome.—Dr. Antonio Ceci has been appointed Professor of Surgical Pathology.

St. Petersburg (Princess Helena Pavlovna Clinical Institute).—Dr. Anrep, formerly professor in Kharkoff, has been appointed Professor of Medical Jurisprudence. Drs. Nikitin and Tiling have been appointed *docents* in laryngology and surgery respectively.

Turin.—Dr. Pagliani has been promoted to the Professorship of Hygiene.

THE death of Sir William McArthur, which occurred suddenly, after hurrying to catch a train on the Metropolitan Railway on Wednesday morning last, should not be allowed to pass unnoticed by us. Amidst his philanthropic exertions, his zealous promotion of the Metropolitan Hospital Fund during his mayoralty was most conspicuous, and the financial efficiency of the London medical charities was a subject very near his heart. His occupancy of the civic chair in 1881 was also signalised by the reception at the Mansion House of the members of the International Medical Congress held in London in that year.

FROM the report on the composition and quality of daily samples of the water supplied to London, made by Messrs. Crookes, Odling, and Tidy, to the Water Examiner appointed under the Metropolis Water Act, 1871, it appears that the supply during October was found practically identical in character with that of the preceding three months. All the samples alike from the Thames and the Lea were free from turbidity, and unexceptionable in respect to colour; while the proportion of organic matter present was but small, and very uniformly so, in the different samples examined.

A CHANGE is announced in the editorship of the *St. Petersburger Medicinische Wochenschrift*, Dr. Th. v. Schröder of St. Petersburg, taking the place of Dr. Gustav Tiling. The other members of the editorial staff, Professor E. von Wahl of Dorpat, and Dr. L. von Holst of St. Petersburg, remain unchanged.

WE regret to learn that, on account of illness, Mr. Francis Galton, the President of the Anthropological Institute, was unable to commence his course of three lectures upon "Heredity and Nurture" at the South Kensington Museum on Saturday last. The lectures have been indefinitely postponed.

THE first of a course of post-graduate lectures on Diseases of the Skin was given by Dr. R. M. Simon in the library of the Medical Institute, Birmingham, on the 15th inst. There was a large and appreciative audience, and the lecture was amply illustrated by patients, diagrams, and therapeutic preparations.

MESSRS. P. AND D. COLNAGHI AND CO. have submitted to us a fine etching of Dr. William Harvey, from the picture by Cornelius Janssen, in the collection of the College of Physicians, London. The portrait is an excellent work of art.

WE understand that the appointment of Obstetric Physician to St. Thomas's Hospital has been deferred, Dr. Gervis having agreed, at the request of his colleagues, to postpone the date of his retirement.

DR. OCTAVIUS STURGES has been appointed Assessor to the Regius Professor of Physic in Oxford University.

Digitized by Google

THE CASE OF

HIS IMPERIAL HIGHNESS THE CROWN PRINCE OF GERMANY,

FROM THE TIME OF HIS VISIT TO ENGLAND TILL HIS ARRIVAL AT SAN REMO.

BY SIR MORELL MACKENZIE.

(*From notes supplied by* Dr. NORRIS WOLFENDEN *and* Mr. MARK HOVELL.)

AFTER the removal of the growth last summer, and the subsequent application of electro-cautery, no recurrence of the growth took place. Some general congestion of the larynx remained, and whilst His Imperial Highness was in the Isle of Wight a slight thickening of the mucous membrane on the posterior surface of the arytenoid cartilages near their base was observed by Dr. Norris Wolfenden, at that time in daily attendance on the Crown Prince. At one of my weekly visits I verified Dr. Wolfenden's report, and perceived that the thickening presented the form of a ridge, raised to the extent of about a millimetre, of yellowish colour, and extending horizontally from the outer border of one cartilage to that of the other. The action of the left vocal cord, which had been noticed in Berlin to be slightly impaired, continued in the same state. It should, perhaps, be here mentioned that soon after His Imperial Highness arrived in England a marked disposition to catarrhal inflammation of the larynx and trachea, or fugitive congestion, was observed. A rather sharp attack occurred in the Isle of Wight, and this was followed by general relaxation of the mucous membrane of both the pharynx and larynx. The congestion disappeared whilst the Crown Prince was in the Highlands, and during this period the thickening at the base of the arytenoid cartilages already described was absorbed. On the return of His Imperial Highness to London the condition of the larynx was on the whole satisfactory; the movement of the left vocal cord was much more free, and the voice strong though not quite clear, owing to a slight increase in the congestion having taken place on leaving Braemar. The Crown Prince's general health was excellent.

On Sept. 9th a slight thickening was noticed on the posterior extremity of the left vocal cord, which increased for a few days, and then gradually disappeared, being on the 18th no longer visible. For a few days previous to the development of this thickening the larynx generally had again been more congested. On Sept. 13th Dr. Evans of Paris extracted the Crown Prince's left lower second molar tooth, which was much decayed, the fangs showing the result of a considerable amount of periostitis.

On Sept. 14th an oblong thickening of the mucous membrane, about five millimetres in length and three in width, was observed by Mr. Mark Hovell nearly half an inch below the middle of the left vocal cord and parallel with its free border. Mr. Hovell states that this swelling gradually increased in size, and when seen by me on Sept. 22nd it was nearly round, and measured rather more than half a centimetre in diameter. Two days later the Crown Prince took cold, and on the following day complained of a sense of fatigue, disinclination to take food, and great sleepiness in the daytime. On examining his throat, the left ary-epiglottic fold was found to be œdematous. His temperature was 101° F. In twenty-four hours the œdema had entirely disappeared, and the temperature had become normal. Although the œdema was apparently due to cold, the possibility of its being caused by limited perichondritis was discussed at the time. The acute swelling had no apparent effect on the little thickening below the left vocal cord, *which gradually became smaller, but did not entirely disappear.*

The Crown Prince continued to enjoy good health after his arrival at Baveno, and when I left Italy everything appeared satisfactory, though slight general congestion remained, as well as the thickening referred to previously. On the evening of Oct. 17th Mr. Mark Hovell noticed a marked increase in the congestion of the larynx, both vocal cords being of a bright-red colour. During the next few days the congestion decreased, but on the 21st the hyperæmia again increased in intensity, and was more diffused. On the 27th an increase was noticed in the size of the thickened surface beneath the left vocal cord, and at the same time slight general tumefaction of the left side of the larynx appeared. During the next few days the thickened surface slightly increased, and on the 31st the surface was seen to be irregular, and in one place there was a distinct spur or projection. The next day superficial ulceration of the new formation was noticed, and the left vocal cord was seen to be slightly swollen along its free edge. On the 28th the voice of His Imperial Highness was quite clear, and, indeed, in the opinion of the Crown Princess, was perfectly natural; but since this date the Crown Prince had been much more hoarse. On Oct. 30th a slight reddish projection was noticed beneath the *right* vocal cord; this remained stationary for two or three days, then disappeared, and formed again on Nov. 5th. On Nov. 1st a slight enlargement of the left submaxillary gland was noticed, and this subsequently increased in size.

On Nov. 3rd, the new formation had further enlarged, and was now rather more than a centimetre in diameter, and raised to the extent of about four millimetres. The extension of the growth since it was first seen had always been upwards. On the morning of the 4th, a very slight œdema was noticed at the base of the left arytenoid cartilage, which disappeared in the evening, and was again present on the morning of the 5th.

On the following day I arrived and found the state of the larynx such as Mr. Hovell had described to me. On the afternoon of the 8th, intense œdema of the mucous membrane covering the left arytenoid cartilage was noticed, and in the evening the œdema involved the entire fold, which was tense and red. On Nov. 9th the patient was examined by Professor Schrötter and Dr. Krause, but owing to the œdema it was impossible to obtain a complete view of the new formation at the lower part of the larynx. On Nov. 10th the patient was again examined by the same physicians, and also by Dr. Moritz Schmidt; the œdema was already much diminished, and a good view could be obtained of the whole of the larynx.

In my opinion the œdema is due to limited perichondritis, which, in its turn, has probably been set up by the growths which have been formed from time to time in the larynx. Although the nature of the growth which has lately appeared has not been determined by microscopic examination, it presents every appearance of cancer.

The above report is published by the wish of His Imperial Highness the Crown Prince of Germany. A copy of it was sent on Monday to the *Berliner Klinische Wochenschrift.*

INJURIES DURING THE RIOTS.

BY the courtesy of the Surgical Registrars of the Middlesex, St. George's, Charing-cross, and Westminster Hospitals, and the house-surgeons of St. Thomas's and King's, we are enabled to give a few interesting particulars of injuries received during the rioting in Trafalgar-square on Sunday, the 13th. We do not pretend to give a detailed list of those injured. This would be impossible, the number being unknown; but several were treated at Bow-street by Mr. Mills, who was busily employed for some time, and others were treated in or near the Square. It will be seen that Charing-cross Hospital was most busily employed, its proximity to the seat of the disturbance being well known. At this hospital patients were attended to for the following injuries: — Shock 1, contusion of face 6, head 3, arm or hand 6, abdomen 2 (of which one was admitted for a few hours), foot 1; wounds of the scalp 40, face 2, arm 1, hand 2, finger 2, leg 1, bayonet wound of buttock 1, punctured wound over the eye 1. One was also seen for a slight burn on the neck, due to corrosive fluid thrown from a squirt. At Westminster 27 were attended to: 18 for wounds of the scalp, 2 incised wounds of the face, 2 contusions of the arms, 2 contusions of legs, 2 contusions of the abdomen (kicks from horses), 1 incised wound behind the right shoulder (policeman). At St. Thomas's Hospital from fifteen to twenty cases were treated. Of these the great majority were contused scalp wounds, chiefly

Digitized by Google

of a superficial character, and occupying the occipital and parietal regions; two or three extended to the bone. In only one case were there two wounds on the same patient. The wounds were nearly all linear in appearance. One patient was attended for fracture of the right ulna in the lower third produced by direct violence. Only two cases were admitted, one a youth with severe concussion and fracture of left clavicle, the other a mounted policeman, who received an injury to the hip from his horse falling and rolling upon him. Both are now doing well. About fourteen casualties, some of a serious nature, were treated at the Middlesex Hospital, chiefly contused wounds of the head and upper limbs. A case of cut lip, another of cut eye, an injury to the arm, and five cases of scalp wounds were treated at King's College Hospital. At St. George's Hospital a few scalp wounds and hæmatomata of the head, and a fracture of the clavicle in an old woman who had been knocked down by the crowd, received treatment.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sheffield Urban District.—Reporting on the health of this borough during 1886, Dr. Sinclair White records a death-rate of 19·7 per 1000, which is 0·9 lower than that for any previous year as to which information is available, a circumstance which involves not only some substantial saving of life, but a corresponding higher degree of vitality in the living by lessening sickness, and hence less poverty and misery. The birth-rate is also the lowest on record. The death-rate from zymotic diseases was 2·88 per 1000, and of the deaths included there were 133 from scarlet fever, 447 from diarrhœa, and 160 from whooping-cough. Dealing with tubercular diseases, Dr. White refers to the possibility that tubercle may be communicated to man by supplying as food the flesh or milk of animals who have already developed the disease, and he considers that just as the danger from food is rendered remote by cooking, so it may be staved off by the boiling of milk. And this leads him to speak generally of the importance, in view of recent researches in bacteriology, of paying great regard to our sources of food supply. As to scarlet fever, the investigations carried out in Sheffield have not as yet tended to connect that disease with the milk service or with any bovine affection. Dealing with the question of the notification of infectious diseases, Dr. White explains that a voluntary system has been in operation since the middle of 1885, and that it has been very helpful. But he cannot say that such a system is satisfactory; its imperfections are numerous, and it breaks down at the most critical point. Lead poisoning still continues in Sheffield from the use of the Redmires water, on which Dr. White reported at length some time since, and the danger is, in his opinion, one that ought forthwith to be dealt with. The report dwells also at length on the nuisance and danger to health arising from the midden-privy system; and in discussing the remedy, prominence is given to the excellent results following on the use of the trough-closet as now constructed with automatic means of flushing. In a record of ordinary sanitary work, we find that disconnexion of house drains has been carried out in no less than 3000 houses, a piece of work that represents a most important effort in getting rid of dangers to public health. The report, like others issued by Dr. Sinclair White, is a document containing an excellent record of work done, and it bids fair to act as an incentive towards still better work in the future.

Salford Urban District.—Dr. Tatham, in his annual report for 1886, calls the attention of the sanitary authority once again to the existence of certain areas which are so wanting in health requisites as to constitute a constant source of danger and of high mortality to the borough. The sewerage in these parts is bad; the state of the Irwell is filthy; the removal of night soil is most objectionably carried out; and the private slaughter-houses constitute a nuisance. On one point Dr. Tatham speaks most emphatically: he declares that until the midden system shall have been entirely and permanently banished from the borough the public health there will never be finally satisfactory. The action of the Manchester and Salford Sanitary Association, and the labours of the ladies and mission women connected with it, receive a grateful recognition; and a record of the services of that body shows how much it has done to improve the conditions of life under which the people live. The annual death-rate for 1886 was 23·7 per 1000 living, and this shows that ground has been lost during the year. The excess was not due to any special disease, although diarrhœal and tubercular affections were more than usually prevalent. In dealing with typhus, Dr. Tatham calls attention to the circumstances under which that disease was imported into the borough by means of gipsies who had been attending a neighbouring fair in their vans, and he refers to the fact that these gipsies moved about in their caravans until, in the end, they could no longer be traced. The story shows strongly the need for the compilation of bye-laws under the recent Act as to the housing of the working classes &c., and for a clause definitely prohibiting the removal of any van containing infectious disease, except under the authority of the sanitary officers. Referring to the compulsory notification of infectious diseases, it is recorded that whereas prior to that system coming into force only 14 per cent. of the scarlatina deaths occurred in public institutions, since its adoption 42 per cent. have occurred in the borough fever hospital. And since the notification has been in force a material reduction has taken place in the rate of that mortality. Appended to the report is an excellent paper, to which we have before alluded, as to the principles which should be held in view by the Town Council in the erection of the new infectious hospital which is in contemplation.

Bethnal-green.—The annual death-rate for 1886 was 23·4 per 1000, which is not only in excess of that for the previous year, but much in excess of the metropolitan rate, which was 19·9. Nearly half the deaths were of children under five years of age, and of those under one year the death-rate amounted to 171 per 1000 births. Of the principal zymotic diseases there were 507 fatal attacks, the heaviest number of deaths being 162 from diarrhœa, 148 from whooping-cough, and 108 from measles. All the various diseases causing death are dealt with in groups, and the conditions leading to them are in some cases considered. The Washington Lyon steam disinfector gives satisfaction, and from Dr. Bate's account of the general sanitary proceedings it is evident that a good deal of attention is now directed to the promotion of health in this metropolitan district.

St. Pancras.—In this district the death-rate was 20·1 per 1000 last year; the deaths under one year being 15·1 per 1000 registered births. During the year 290 rooms were fumigated, and a large number of infected articles were dealt with in the disinfecting stove. Whereas the density of population for the metropolis generally was 54 persons per acre in 1881, it has now reached 90 in St. Pancras; and Dr. Sykes finds it necessary to warn the vestry of the extreme importance of retaining such open spaces about houses as can be secured. Amongst the dwellings in which air is obstructed, he refers to cellar dwellings, back-to-back houses, and enclosed dwellings; the latter term relating to some that are obstructed on all sides. As regards such description of accommodation, he recommends that action shall be taken, even if it must be deferred until the expiration of the present leases. Dealing with overcrowding, Dr. Sykes refers to 300 cubic feet as being sanctioned for day and night purposes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5872 births and 3548 deaths were registered during the week ending November 12th. The annual rate of mortality in these towns, which had been 21·5 and 21·4 per 1000, further declined last week to 20·0. During the first six weeks of the current quarter the death-rate in these towns averaged 19·7 per 1000, and was 1·0 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 9·3 in Brighton, 12·2 in Plymouth, 14·1 in Norwich, and 14·5 in Sunderland. The rates in the other towns ranged upwards to 27·0 in Preston and in Halifax, 29·6 in Oldham, and 28·3 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 464 and 466 in the preceding two weeks, declined last week to 402; they included 111 from scarlet fever, 82 from measles, 58 from

Digitized by Google

whooping-cough, 53 from "fever" (principally enteric), 43 from diphtheria, 37 from diarrhœa, and 18 from small-pox. No death from any of these zymotic diseases was registered last week in Plymouth, Wolverhampton, or Cardiff, while they caused the highest death-rates in Salford, Bradford, and Sheffield. The greatest mortality from scarlet fever occurred in Norwich, Manchester, Bristol, Salford, Oldham, Birkenhead, and Blackburn; from measles in Derby, Blackburn, Bolton, Birmingham, and Bradford; from whooping-cough, in Birkenhead; and from "fever" in Derby and Preston. The 43 deaths from diphtheria in the twenty-eight towns included 30 in London and 2 in Manchester. Small-pox caused 17 deaths in Sheffield, and 1 in London, but not one in any of the twenty-six other large provincial towns; the 13 cases of small-pox under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease corresponded with the numbers at the end of the previous week. The number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had further increased to 2751 at the end of the week, although the number of admissions showed a decline. The deaths referred to diseases of the respiratory organs in London, which had steadily increased in the six preceding weeks from 206 to 506, declined again last week to 438, but exceeded the corrected average by 14. The causes of 76, or 2·2 per cent., of the 3548 deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Leicester, Portsmouth, and in six other smaller towns. The largest proportions of uncertified deaths were recorded in Preston, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·2 and 20·6 per 1000 in the preceding two weeks, further declined to 19·9 in the week ending Nov. 12th; this rate was 0·1 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·1 and 16·2 in Aberdeen and Perth, to 23·3 in Greenock and 29·1 in Paisley. The 498 deaths in the eight towns last week showed a further decline of 17 from the numbers returned in recent weeks, and included 26 which were referred to whooping-cough, 17 to scarlet fever, 10 to diphtheria, 8 to diarrhœa, 7 to measles, 6 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 74 deaths resulted from these principal zymotic diseases, against 70 and 66 in the preceding two weeks. These 74 deaths were equal to an annual rate of 2·9 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 26 in each of the preceding two weeks, were again 26 last week, of which 9 occurred in Glasgow, 6 in Greenock, and 3 in Dundee. The deaths from scarlet fever, which had declined in the preceding four weeks from 23 to 14, rose again last week to 17, and included 7 in Dundee, 5 in Glasgow, and 2 in Greenock. The 10 deaths from diphtheria exceeded the number in any recent week, and included 7 in Glasgow and 2 in Greenock. The 8 deaths from diarrhœa, however, corresponded with the number in the previous week, and were 13 below that in the corresponding week of last year. The 6 deaths referred to "fever," of which 2 occurred in Edinburgh and 2 in Greenock, corresponded with the number returned in each of the preceding three weeks. The 7 fatal cases of measles, however, showed a slight further increase upon recent weekly numbers, and included 3 in Perth, 2 in Edinburgh, and 2 in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding five weeks from 87 to 131, declined last week to 107, and were 16 below the number returned in the corresponding week of last year. The causes of 71, or more than 14 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 32·1 and 31·0 per 1000 in the preceding two weeks, rose again to 32·1 in the week ending November 12th. During the first six weeks of the current quarter the death-rate in the city averaged 28·5 per 1000, the mean rate during the same period being but 19·0 in London and 18·2 in Edinburgh. The 217 deaths in Dublin last week showed an increase of 7 upon the number in the previous week; they included 20 which were referred to scarlet fever, 10 to measles, 6 to diarrhœa, 5 to whooping-cough, 3 to "fever" (typhus, enteric, or simple), 1 to small-pox, and not one to diphtheria. Thus, the deaths resulting from these principal zymotic diseases, which had been 29, 42, and 41 in the preceding three weeks, further rose last week to 45; they were equal to an annual rate of 6·6 per 1000, the rate from the same diseases being 2·4 in London and 1·4 in Edinburgh. The fatal cases of scarlet fever, which had been 8, 11, and 19 in the previous three weeks, further rose last week to 20; the fatal cases of measles and of whooping-cough also showed an increase upon recent weekly numbers. The deaths from "fever," on the other hand, had considerably declined. Nine inquest cases and 4 deaths from violence were registered; and 51, or nearly a fourth, of the deaths registered in the city during the week were not certified.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the following promotions among the officers of the Staff Corps and Indian Military Forces made by the Governments in India:—Surgeon-Major David John McCarthy, M.D., of the Madras Medical Establishment, to be Brigade Surgeon (dated Aug. 1st, 1887); Surgeon Edward Ferrand and Surgeon Francis Hoskins Pedroza, of the Madras Medical Establishment, to be Surgeons-Major (dated Sept. 30th, 1887). The Queen has approved of the retirement from the Service of the undermentioned officers of the Indian Military Forces:—Deputy Surgeon-General Lewis Stanhope Bruce, of the Bombay Medical Establishment (dated Sept. 15th, 1887), and Brigade Surgeon Charles Edwin Raddock, of the Bengal Medical Establishment (dated Aug. 6th, 1887). The Queen has approved of the undermentioned Officers being granted a step of honorary rank on retirement:—Deputy Surgeon-General Henry Walter Bellew, C.S.I., of the Bengal Medical Establishment (dated Nov. 14th, 1886), and Deputy Surgeon-General Lewis Stanhope Bruce, of the Bombay Medical Establishment (dated Sept. 15th, 1887), to be Surgeons-General; Brigade Surgeon C. E. Raddock, of the Bengal Medical Establishment (dated Aug. 6th, 1887), to be Deputy Surgeon-General; and Surgeon-Major William Nolan, M.D., of the Bombay Medical Establishment (dated Sept. 24th, 1887), to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon A. Gorham, to the *Téméraire;* Staff-Surgeon W. P. M'Boyle, to the *Shannon;* Staff Surgeon A. Patterson, to the *Victor Emmanuel;* Staff Surgeon W. F. Spencer, to the *Ajax;* Surgeon J. F. Kellard, to the *Mutine;* Surgeon J. M. France, to the *Shannon;* Surgeon J. Crowley, to the *Urgent;* Surgeon G. T. Brostch, to the *Excellent;* Surgeon E. H. Menden, to the *Téméraire;* Surgeon J. W. O. Underhill, to the *Assistance;* Surgeon H. L. Crocker, to the *Carysfort;* Surgeon B. C. E. F. Gunn, to the Chatham Hospital; Surgeon E. J. Fogerty, to the *Cruiser;* Surgeon J. S. Jackson, to the Walmes Depôt of Royal Marines; Fleet Surgeon Frederick M'Clement, to the *Dreadnought;* Fleet Surgeon Wm. B. Wadsworth, to the *Northumberland;* Staff Surgeon Joseph Wood, M.D., to the *Agamemnon;* Staff Surgeon Chas. L. Vasey, to the *Active;* Surgeon Alexander G. P. Gipps to the *Dreadnought;* Surgeon F. M. Puddicombe, to the *Agamemnon;* Surgeon A. J. J. Johnston, to the *Asia;* and Surgeons Robert M'Ivor and Horace Elliott, to the *Northumberland.*

RIFLE VOLUNTEERS.—1st Ayrshire: John Moyes, M.D., to be Acting Surgeon (dated Nov. 12th, 1887).—18th Middlesex: Acting Surgeon J. E. Lane resigns his appointment (dated Nov. 12th, 1887).

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—The autumn general meeting will be held at 49, Berners-street, Oxford-street, on Wednesday next, the 23rd inst. The chair, to be taken at 5 P.M., will be occupied by the President, Sir Thomas Crawford, K.C.B. The Council will report further proceedings with reference to the exclusion of those holding Irish medical degrees and the higher diplomas of the K.Q.C.P.I. and of the R.C.S.I. from English hospital appointments. The Association dinner will take place at the Holborn Restaurant at 7 P.M. the same evening, Sir Thomas Crawford in the chair.

"Audi alteram partem."

THE DISCUSSION ON CARDIAC MURMURS.

To the Editors of THE LANCET.

SIRS,—Permit me to correct a misunderstanding of my remarks at the Medical Society of London last Monday. I am reported to have said that I differed from Dr. Gairdner as to the mode of production of the murmur which is pathognomonic of mitral stenosis. I wished to assert, on the other hand, that I entirely agreed with Dr. Gairdner's explanation of the cause of the murmur. My valued friend knows this full well, for I have had the advantage of his co-operation in examining patients manifesting the murmur in my wards in the London Hospital. Our only difference, as I tried to make clear at the Medical Society, is on the point of nomenclature. I object to the term "auricular-systolic" as applied to the murmur, because it seems to define that the systole of the auricle is *alone* the cause of the sound, whereas we are agreed that this may be produced anteriorly to the auricular contraction. I prefer the term "presystolic," because I could connote by this a murmur commencing not with but after the second sound, and occupying the whole or any part of the long pause until the succeeding first sound. I am, Sirs, yours truly,

A. ERNEST SANSOM, M.D.

Harley-street, Cavendish-square, W., Nov. 13th, 1887.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—In 1864, when practising in Nottinghamshire, I was consulted by a labouring man, in middle life, suffering from extensive epithelioma of the lower lip, which eventually caused his death. He always attributed the cause of his complaint to drinking daily out of the same vessel as his father, who died a year previously from epithelioma of the lip. This, if nothing more than a coincidence, is momentarily interesting.

This is the only instance that has ever come under my notice which would support the theory of cancer being contagious. I am, Sirs, yours truly,

Manchester, Nov. 12th, 1887. WALTER WHITEHEAD.

"HEMIPLEGIA DURING THE PUERPERIUM."

To the Editors of THE LANCET.

SIRS,—After reading the interesting case by Dr. S. Sloan in THE LANCET of Oct. 1st, I looked over my scribbling note-book, and found the following note, which you may think might interest your readers:—

Mrs. F—— was delivered by a nurse. The delivery was natural and easy, notwithstanding that ten days previously she had a row, and, I heard, a stand-up fight with one of her female neighbours. The child dying suddenly on the fourth day brings me on the scene with a coroner's order to report on the probable cause of death, which was from natural causes. There was nothing out of the way to draw my attention to the mother, but three days after I am asked to see her, and find her in a semi-conscious state, her hand to her head complaining of pain, bosom swollen and hard, bowels costive, lochia flowing. Under ordinary treatment these symptoms cleared up; but on my usual visit on the seventh morning, I again find her semi-conscious, her mouth drawn to the right side, her left arm and leg quite paralysed, and no control over either bladder or bowel. Here my note ends, for soon afterwards she was removed to the workhouse, and I know after some months she returned home able to do her household duties. Her previous history is this: Always subject to epileptic fits; this was her second child; no fits either during or after labour; parents never "very clever." In this case you will see the hemiplegic symptoms did not show themselves until the fourteenth day after confinement. As to her heart, I believe that was and is quite healthy.

I am, Sirs, yours truly,

Ashburton, Devon, Nov. 9th, 1887. WILLIAM FRASER, M.B.

SCARLET FEVER; SECOND ATTACK.

To the Editors of THE LANCET.

SIRS,—On October 10th I sent a child to the Fever Hospital with scarlatina, well-marked symptoms, sore throat, and scarlet efflorescence on wrists. The patient was returned from the hospital as cured a few days ago, and on Nov. 6th I was called to see the patient, who, I found, was suffering from a second attack, and consequently I had to order the patient to be sent to the hospital a second time, which I should consider rather an unusual occurrence. If you consider it to be so, perhaps you would insert this in your valuable journal. I am, Sirs, yours truly,

Nov. 8th, 1887. M.R.C.S.

*** Such cases as the above are undoubtedly rare. In THE LANCET of July 21st, 1883, a somewhat similar case was reported as occurring in the Leeds Fever Hospital, under the care of Dr. Barrs.—ED. L.

THE PROFESSION AS A CALLING *v.* QUACKERY. THE CORPORATIONS AS GUARDIANS OF PROFESSIONAL INTERESTS.

To the Editors of THE LANCET.

SIRS,—It is with wonder that I read from week to week, in your valuable journal, the numbers of men entering the medical profession or commencing their studies, lectures, hospital practice, &c., at the various schools. I ask myself, Have these men well considered what they are doing? Have they sat down and counted the cost of time, study, and pecuniary outlay? If so, for what? I am a general practitioner, with an average income from my practice. I am an M.D. of a university; this gives a status if you have money. I am a surgeon; a "bone-setter" near me gets larger fees and better income. I am an apothecary; a chemist close by visits and prescribes. It may be thought by these young men that the universities, colleges, or examining boards, who derive large incomes from fees &c., will protect their rights, interests, &c. I never heard of their so doing. I therefore say to these men, Think twice before you endeavour to enter the profession for a living, when you can practise with equal success as a quack, without the expenditure of your capital, time, and brains. Such is the advice of one who is looked upon as a well-to-do, successful REGISTERED PRACTITIONER.

November, 1887.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

TYNEMOUTH INFIRMARY.

AT a meeting to promote the erection of a hospital for the borough of Tynemouth, and presided over by Mr. H. S. Donkin, M.P., it was mentioned that the project was in a fair way of being realised, but that £1000 were still wanted to complete the erection. The chairman mentioned that a gentleman in the borough had promised him £250 of the amount provided the balance was raised in six months. Before separating the meeting pledged itself to raise the necessary sum within six months.

YOUNG CHILDREN IN A WORKHOUSE.

At a late meeting of the Auckland guardians, co. Durham, the very large number of young children in the workhouse was commented upon. A guardian had counted nineteen children in arms, and thought they should, as guardians, prevent the workhouse being turned into a lying-in hospital.

A SHIELDS BATHER'S RECORD.

Mr. Joseph Pollard, swimming master, South Shields, has completed ten years of sea bathing. With the exception of forty mornings, he has bathed continuously. The actual number of dips for the ten years was 3612, and in walking to and from the seaside for these baths Mr. Pollard has travelled 6772½ miles. The omissions were caused by illness, brought on by Mr. Pollard's attempt to swim from New-

Digitized by Google

castle to Shields, in August, 1884. Mr. Pollard still continues his bathing, and although well advanced in years he is in excellent health.

DEATH OF MR. WILLIAM CARR AND DR. J. C. MURRAY, LATE OF NEWCASTLE.

I regret to notice the rather sudden death of Mr. William Carr, M.R.C.S., of this city, which took place on Nov. 7th. He was in his seventy-sixth year, and was one of our oldest general practitioners. He was a pupil of the late Sir John Fife, and had been in active practice in Newcastle for half a century. He was a widower, and had also the misfortune to lose two sons by death, who were fully qualified and assisted him in his practice, which at one time was an important one, but of late years he mostly restricted his services to his old friends who remained as patients. Mr. Carr has left one daughter as his sole survivor. He was very active when in good health, and did a large amount of work outside his profession as churchwarden &c. He also contested a vacant coronership with much spirit a few years ago, and, although not successful, he earned the gratitude of the profession, for it is well understood that it was the principle rather than the emoluments of the office he fought for. Mr. Carr's health had been evidently failing for some time, but he got about up to the day of his death. I saw him on that day in the forenoon at the Exchange News Rooms. Soon afterwards, it appeared, he was taken ill in the streets, and, hailing a hansom, was driven home, where he was enabled with help to recline on a sofa. His neighbours, Drs. Embleton and Stainthorpe, were speedily on the spot, but found that their friend had passed away from syncope.—Dr. John Cass Murray, who had been many years in practice in Newcastle, also died last week at Stranraer, where he had retired from active practice a few years ago owing to failure of health. Dr. Murray was one of the founders of the Chest Hospital in this city; he was a ready writer, and, as well as being a regular contributor to the medical journals, he published a very successful *brochure* on the Use and Abuse of Tobacco, which has had a large sale, and was very favourably reviewed by the medical journals as a treatise; but his views as to the advantages of tobacco in chest diseases were peculiar, and will hardly be adopted by the profession. Dr. Murray, who was in his fifty-fifth year, has left a widow and grown-up family of four daughters and one son.

Testimonials of respect have been given by friends and patients to Drs. Rennie of Cullercoats and Paxton of Norham. The latter received a jubilee gift, having practised in Norham for a period of fifty years.

Newcastle-on-Tyne, Nov. 15th.

EDINBURGH.

(From our own Correspondent.)

HEALTH SOCIETY LECTURES.

THE first of the annual series of Health Lectures for the People was delivered by Dr. T. S. Clouston last Saturday night. Taking as his subject, "How pleasant Surroundings and Conditions affect Health and Happiness," the lecturer stated, and illustrated by a series of striking instances, the general principle, that whatever outward conditions contribute to growth, strength, and perfection of structure, and promote normal function, tend directly to the production of conscious happiness or to the maintenance of a condition of calm equilibrium, which he terms "organic satisfaction." Using this statement of physiological principles as a text, Dr. Clouston preached an admirable and lucid lay sermon on the gladdening and health-giving powers of sweetness and light; nor was the opposite side of the picture left unpainted, for he describes in realistic colours the sort of life that exists in some of the "dark places of the earth." That tendency of human nature which in pleasant surroundings found its expression in innocent gaiety and enjoyment, was identical with that which, in an opposite environment, was the direct cause of indiscretion and excess, with all their train of crime and misery. Alluding to the law of heredity, he showed how the effects of these gloomy surroundings were implanted in the brain before the child was actually conscious of their objective existence, and he gave an ominous warning of what the effect must be when this is continued generation after generation. In concluding his lecture, which was listened to with marked attention by a large audience of the general public, he drew attention to the good done by open spaces, recreation grounds for various forms of exercise and pastimes, and the importance of making schools, hospitals, and other public buildings as bright and cheerful as may be. While acknowledging that much good has been done in these directions, he urged that with increased knowledge of the importance of such reforms, increased efforts should be made on all hands for their accomplishment.

Edinburgh, Nov. 15th.

DUBLIN.

(From our own Correspondent.)

M'GOVERN'S ALLEGED CURE FOR HYDROPHOBIA.

A CONSIDERABLE number of people believe in the efficacy of M'Govern's treatment, while, on the other hand, those sceptical as to the invariably successful result of the cases treated by this method are not few in number. One of the latter (Dr. Thompson of Omagh), in order to test the matter has recently offered a sum of £50 to anyone who can prove an authentic cure by M'Govern; but up to the present no attempt has been made to claim the money.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Council will, at a meeting to be held on Thursday, the 17th inst., elect one additional examiner in Pathology, and one additional examiner in Ophthalmic and Aural Surgery, to examine candidates for the conjoint diplomas of the College and the Apothecaries' Hall.

THE COLLEGE OF SURGEONS AND THE APOTHECARIES' HALL CONJOINT SCHEME.

The examinations under this scheme have been unavoidably postponed in consequence of the action of the College of Physicians, who last week lodged a *caveat* against the scheme.

THE DUBLIN MEETING OF THE BRITISH MEDICAL ASSOCIATION.

A sum of £66 3*s.* 10*d.* (including interest allowed by the bank) having been left over all expenses incurred at the recent meeting of the British Medical Association in Dublin, a meeting of the subscribers to the Reception Fund was held last week in order to dispose of the amount. After some discussion the following resolution, proposed by the Registrar-General and seconded by Sir William Stokes, was unanimously adopted:—"That the surplus should be applied to procure a portrait of Dr. Banks, the President of the Association, to be hung in the hall of the King and Queen's College of Physicians, as a memorial of the Dublin meeting of the British Medical Association in 1887, and of the able, courteous, and efficient manner in which he presided over the meeting." A committee has been appointed to make all necessary arrangements in furtherance of the resolution. At the same meeting a vote of thanks was passed by acclamation to Dr. Duffey for the able manner in which he acted as general secretary during the meeting of the Association in Dublin.

HEALTH OF IRELAND FOR SEPTEMBER QUARTER.

The birth-rate for the quarter was 0·1 over the average rate for the corresponding quarter of the past five years, and 0·3 above the rate for the third quarter of 1886. The deaths exceeded those registered in the September quarter of last year to the extent of 1141. Compared with the returns of pauperism furnished by the Local Government Board for the corresponding quarter of 1886, there is a slight increase in the average number of workhouse inmates on Saturdays during the quarter, but a decrease of 6196 in the average number of persons on out-door relief. The Registrars report the presence of the following diseases in their respective districts—viz., small-pox in 3 districts, measles in 37, German measles (rötheln) in 4, scarlatina in 40, whooping-cough in 46, diphtheria in 10, and fever in 43.

SMALL-POX IN DUBLIN.

Sir Charles Cameron, Medical Superintendent Officer of Health, has reported that five cases of small-pox have

Digitized by Google

occurred lately in Dublin, and in the same district. Brief details of the outbreak are as follows: The first case was that of a girl, who probably received the infection from a sailor, who lodged in the same house, and who had suffered from an eruption. The second was an infant, who had been nursed by the girl above mentioned. Both these cases were admitted to hospital, the infant dying on Nov. 12th. On the 11th inst. a girl sickened with the disease, and two days afterwards a woman was taken ill with it. A fifth case is that of a girl, who is at present under treatment in her own home; and, as she resides in a house occupied by only one family, she cannot forcibly be removed to hospital. It appears that this last case has been going on since Nov. 3rd; yet no report was made of it to the sanitary authority either by the medical attendant or any of the girl's family. This is a fresh illustration of the necessity for the compulsory notification of infectious diseases in Dublin. Sir Charles Cameron points out that the last epidemic of small-pox in Dublin, which caused 2000 deaths, originated in circumstances resembling the present limited outbreak of small-pox. It is intended to issue posters without delay, recommending vaccination, avoidance of contact with people likely to have the contagion of small-pox in their clothing, and the early notification of cases of the disease to the sanitary authority.

THE ABOLITION OF NIGHT LECTURES.

The non-recognition of night lectures after a certain date by the Senate of the Royal University cannot be regarded as a subject for congratulation. As has been pointed out on more than one occasion, some of the smartest medical students in Dublin have attended night lectures — men who were engaged in business during the day, and had not any other time at their disposal. The writer of this has had considerable experience for many years of both day and night students, and can conscientiously affirm that in energy, earnestness of purpose, intelligence, and general good conduct, night students are in no way inferior to their day brethren.

COUNTY GALWAY INFIRMARY.

The Governors will appoint a resident surgeon to this institution on the 10th prox., at an annual salary of £100, with residence &c.

MERCER'S HOSPITAL, DUBLIN.

The inquiry into the charges brought against the senior surgeon, Mr. E. Stamer O'Grady, M.B., F.R.C.S.I., has been adjourned till the 28th inst.

Dublin, Nov. 15th.

PARIS.

(From our Paris Correspondent.)

HYPNOTISM IN PARIS.

THE experiments related by M. Luys some time back at the Academy of Medicine, which were reported in your columns, are repeated frequently at the Charité Hospital, and continue to draw crowds. The lecture theatre is now too small for all the *badauds* who throng to see the wonderful Gabrielle and the no less celebrated Esther, but the world at large is kept *au courant* with the performances by frequent articles in the public press. If the phenomena observed in the unfortunate creatures who are trained into a state of cunning insanity, and who, like Gabrielle, have passed nearly all their lives in hotbeds of hysteria, only were in question, it would still be profoundly humiliating for the profession in general to see the ridiculous comedy now played passed off upon the unscientific public as an advance in medicine. But matters of far wider importance are at issue. Medico-legal experts here have recently acquitted a shop-lifter because she could be hypnotised. There was auto-suggestion, and, consequently, irresponsibility. Professor Brouardel, whose position as dean of the faculty of medicine makes his utterances almost official, has discussed at length both in his lectures and in the medical press (*Gazette des Hôpitaux*) the possibility of the consummation of rape in hypnotised girls, and fully admits it; a conclusion which has been accepted by the Medico-Legal Society. By all means let us have the truth. If past experience be false, which has over and over again unmasked the trickery of these mesmerised, magnetised, or hypnotised subjects, let the question be reopened and examined dispassionately and scientifically, but let the experiments be surrounded with the necessary safeguards to make them an exact test. I for one am convinced that the action of medicine *à distance* would fail under these circumstances, and little would remain of hypnotism beyond perhaps the induction of nervous sleep. But if responsibility is in reality a delusion, and virtue no defence against lust, the sooner our prejudices in these matters are swept away the better. THE LANCET has before this exposed frauds and delusions of the kind, but never was an independent inquiry more needed than at present.

THE ACTION OF MEDICINES *à distance*.

It may be remembered that the experiments upon hysterical patients, with different medicines in sealed tubes, performed by M. Luys, and to which such a notoriety has been given by the press, were originated by MM. Bourru and Burot. The first-named gentleman has been endeavouring to obtain a repetition of these interesting phenomena before an unbelieving public, and has signally failed in the attempt. Speaking at the Société de Thérapeutique, M. Constantin Paul said that he had placed at M. Bourru's disposal a most sensitive subject, upon whom he was allowed to act without any extraneous influence. With a bottle of alcohol *uncorked*, and evidently smelt by the patient, staggering was produced. In another instance, a bottle supposed to contain cherry-laurel water produced effects usually caused by this drug, but it was discovered that the chemist had made a mistake (?), and that the bottle contained water only. Five or six other experiments gave results of the same value. M. Bucquoy said that he was afraid the Commission appointed by the Academy would throw but little light on the question. He could, however, affirm that those of his colleagues and the *internes* with whom he was acquainted were convinced that M. Luys had been imposed upon. M. Voisin, at the Medico-Psychological Society, attributed the results to suggestion. Upon applying an *empty* tube to the neck of one of his subjects, and leading her to suppose it contained alcohol, she immediately showed signs of intoxication. The characteristic effects of other drugs were produced in succession, the patient thinking they were applied, whereas the empty tube was each time substituted. Two months later the experiments were repeated, M. Voisin remarking that the patient would be able to distinguish the drugs from one another. As before, an empty bottle was used, but the therapeutic effects of the drugs were again witnessed, and *in the same order*. Further comment is unnecessary.

NAPHTHOL AS AN ANTISEPTIC.

The antiseptic properties of naphthol have been known for a long time, but owing to the supposed toxicity of this substance, its employment has been till now limited to the local treatment of certain affections of the skin. At a recent meeting of the Academy of Sciences, Professor Bouchard stated that, after two years of research, he has been able to determine and measure the antiseptic power of naphthol as well as its toxic power, and he has been led to conclude that, in certain circumstances, it is to be preferred to all the antiseptics known, owing to its very feeble solubility. To disinfect a surface easily accessible, the soluble antiseptics suffice, and the same should be employed to effect general antisepsia, but none has as yet been found that can be introduced into the blood in sufficient quantity to destroy the vitality of the microbes without compromising the health or life of the patient. To produce antisepsia in the thickness of the tissues, or in that of cavities reached with difficulty, where continued drainage cannot be practised, the insoluble antiseptics, or those only partially soluble, can alone be employed with advantage. They should be preferred for the interstitial treatment of certain maladies of the tissues, for the antisepsia of serous cavities, and particularly for the antisepsia of the digestive tube, which the author has had especially in view in his researches. The explanation on which the advantage of an insoluble antiseptic is founded is that from the fact of its insolubility it is unabsorbable; it will therefore be found present throughout the length of the digestive tube, and can be administered in sufficient quantity to render all fermentation impossible, without having to fear its general action on the economy, into which

Digitized by Google

its insolubility would prevent its penetrating. It was for these reasons that Professor Bouchard preferred the salicylate of bismuth and iodoform; and Rossbach also, when he employed naphthol for intestinal antisepsia. After having tested the antiseptic property of naphthol in certain microbian maladies, Dr. Bouchard found that in a solution of 33 centigrammes to one litre of diluted alcohol the naphthol very much retarded the development of the bacillus of typhoid fever, as well as the germination of the bacillus of tuberculosis. Urine, shaken up with naphthol in powder, then filtered and exposed to the air, does not ferment. According to Dr. Bouchard, the dose of naphthol which may be considered toxic for a man weighing 65 kilogrammes is about 250 grammes. Two and a half grammes of naphthol per day suffice to procure intestinal antisepsia; the author therefore concludes that the toxic power of this substance has been very much exaggerated, though there can be no doubt that a solution introduced into the organism directly through the veins would prove far more dangerous.

SULPHO-BENZOATE OF SODA IN THE DRESSING OF WOUNDS.

At a subsequent meeting of the Academy of Sciences, Dr. H. Heckle, of the Naval Hospital of Toulon, read a note on the results he obtained by the employment of the sulpho-benzoate of soda in the dressing of wounds. These results have been so satisfactory that the author considers this agent as being far superior to all the antiseptics now in vogue, without having any of the inconveniences inherent to them.

DIPHTHERIA AMONGST SOLDIERS.

Since the army surgeons brought to notice the frequency of diphtheria in the French army, particularly among cavalry regiments, Dr. Longuet has studied the subject, and in a paper read before the Academy of Medicine he has arrived at the following conclusion as to the etiology of the disease: "It is incontestable that, not only in the French army, but in the German army, the cavalry, though less numerous than the infantry, furnishes three times more cases of diphtheria. It is equally certain that at Paris, for example, the most active foci of this cruel malady are, on the one hand, the largest of the cavalry barracks, and, on the other, a hospital situated near one of the most important stables belonging to the omnibus company; and, as the cause of the malady could not be traced to the water, nor to the straw, nor yet to the horses, it appears conclusive that it must exist in the manure."

FIRE AT THE ÉCOLE PRATIQUE.

A fire broke out yesterday morning at the École Pratique de Médecine which caused considerable damage. It originated in the laboratory of Dr. Charles Richet, Professor of Physiology, by the over-heating of a gas stove. As the laboratory contained a number of different kinds of essences, these contributed in a great measure to increase the force of the fire, and the whole place was in a blaze in a few minutes, and were it not for the active assistance rendered by the firemen considerable damage might have resulted to the neighbouring buildings. By a curious coincidence, a banquet was arranged for yesterday evening by his pupils to Dr. Charles Richet, son of the eminent Professor of Clinical Surgery at the Hôtel Dieu, who had just been nominated Professor of Physiology at the Paris Faculty of Medicine.

Paris, Nov. 16th.

PROFESSOR MOLESCHOTT ON THE UNITY OF SCIENCE.

(From our Correspondent at Rome.)

THE Roman University began its winter session on the 3rd inst, with a discourse from the Professor of Physiology, Dr. James Moleschott. The great hall of the Sapienza was crowded in every part, and the lecturer was supported on the platform by a distinguished attendance of men of science, of letters, and of public affairs. On such occasions Moleschott, whether addressing a mixed audience or one composed of medical students only, never fails to acquit himself with ability and effect; and his inaugural address was so fully equal to expectation that, by general desire, it will be printed and published for the edification of circles far beyond that of academic Rome. His purpose being to demonstrate the unity of science and the harmony of its various sections, he passed in review the whole array of the *scibile*, setting in relief the reciprocal relations of its components, and leading up to the organic total or harmonious synthesis (*sintesi armonica*). This forms the science of sciences, the true philosophy of the modern time. Before it disappear the artificial classifications, the premature "systems," to give place to a chain whose "continuity" knows no "solution," and of which each individual science is but a link. Palæontology, for example, has given its hand to embryology, to weave again the evolution of living organisms, always more specialised and more complex, but springing from the unbroken series of the transformations and specialisations of organ and function. So the circle of life closes in death, in which again life, like a new Phœnix, finds the germs of another birth. The value of each science in its bearing on general progress was thereafter estimated, the palm being given to mathematics as formulating the True in the rigorous exactness of Number, while in the infinitely various multiplicity of geometrical forms it furnishes to art the eternal principles of the Beautiful. Metaphysics, he continued, created the axiom, which modern science repudiates, as she repudiates "innate ideas." But if metaphysics no longer creates the *scibile*, she gives organic form to the truths ascertained by analysis and generalises their laws, vouchsafing to science that method which is the foundation of inductive research. Besides, in metaphysics lies the basis of ethics, which, soaring to the serenity of the ideal, gives its hand to æsthetics, to form the sublime triad of Plato, the True, the Good, and the Beautiful. No man of science, continued Moleschott, can nowadays isolate himself in a specialty; each of us has need of the aid of the cognate sciences. The physician may no longer seek the causes of disease in the mere influences of the atmosphere, or in the disorders of the passions; but to-day he finds an unexpected auxiliary in botany, which reveals in the ultimate categories of vegetable life the sporules of the lowest parasitic fungi, which are the determining cause of maladies without number. Hence he prepares the human organism through hygiene to resist those enemies to health by denying them the soil in which they germinate. Proceeding to anthropology, which embraces all the manifestations of life, Moleschott dwelt on it by way of transition to the moral sciences, and to politics, which subsists on statistics, up to the social sciences, which, studying society as a living organism, prepare, step by step, the solution of the great questions in which lies the amelioration of the condition of the labouring classes. Scientific progress, concluded Moleschott, has two implacable enemies—ignorance and pessimism. But in the dark one is afraid of a statue, and pessimism has only the courage of despair. Now, "he who despairs," says the poet, "does not work." Only he who works carries in his own conscience the fruit and the guerdon of his life. Loud and continuous plaudits greeted the lecturer as he resumed his seat—the reference to the obscurantist horror of the proposed statue to Giordano Bruno (a "reformer before the reformation," who was burnt for heresy in the Campo dei Fiori) evoking rounds of cheering from the students, with whom the commemoration of Bruno originated. Moleschott, as an accomplished scholar, particularly profound in his knowledge of Dante, as a proficient physiologist, and as an able consultant, has long mastered the secret of charming a cultured audience. His discourse was a brilliant success, and cannot fail in its printed form to give equal delight to still more extended circles than that of his adopted compatriots.

PRESENTATIONS.—Dr. Blomfield, physician to the Exeter Dispensary, on resigning the house-surgeoncy of the Devon and Exeter Hospital, which he held from 1881 to 1887, has recently been presented with a silver teapot, cream-jug, and sugar-basin on an oak tray, by the nurses and servants of the hospital. The teapot bears the following inscription:—"Presented, with a sugar-basin and cream-ewer, to Arthur George Blomfield, Esq., M.D., House-Surgeon of the Devon and Exeter Hospital from 1881 to 1887, as a token of esteem, from the nurses and servants. October, 1887."—Mr. Paxton, of Norham, has been presented with an illuminated address, a carriage clock, and a purse of sovereigns by over 300 of his patients and friends, on his completion of fifty years practice in that village.

Obituary.

JAMES GREY GLOVER, M.B., C.M.
(OF SUNDERLAND.)

GRADUATES of the University of Edinburgh of two or three years' standing will be sorry to hear of the very early death—at twenty-three—of Mr. James Grey Glover, M.B. and C.M. Edin., at Las Palmas, Grand Canary, on Nov. 9th. This feeling will not be unshared by many of the professors to whom his faithful work and bright and genial character were known. To his own family the event is fraught with a great sadness, at once mitigated and enhanced by the memory of his nature and his promise. Shortly after graduating in Edinburgh, in 1885, which he did with honours, Mr. Glover studied for some months at the London Hospital. Thereafter he took an assistantship at Barry, near Cardiff, which he had to relinquish in December of last year, on account of chest symptoms, for which he took a voyage to India, without advantage. He was distinguished in the University for his ability at play as well as work, being among the foremost at cricket, football, cycling, &c. On two occasions he rode from Edinburgh to Sunderland in one day on his bicycle, a distance of 120 miles. He was bent on trying the effects of Las Palmas, but it is only fair to say that his disease was far advanced, and his friends did not share his hopes of the results of the experiment. Mr. Glover was the second and only surviving son of Mr. Terrot Glover of Sunderland, and nephew of Dr. Glover of London.

CHARLES FRANKLIN, M.R.C.S., L.S.A.

IT was with sincere regret that the numerous friends of Mr. Charles Franklin heard of his sudden death on the 4th inst., from heart disease. This occurred at Brighton, where he had been staying for a few days in order to recruit his health. The third son of Henry Franklin, Esq., he was born in Kingston, Jamaica, on Oct. 4th, 1842, and when eight years of age came with his brother to England, and was placed under the care of the late Rev. E. Trimmer of Putney. Afterwards he went to Tonbridge School, where he was under the tuition of Dr. Welldon. He then entered as a student at Guy's Hospital, taking the M.R.C.S. in 1863, and the L.S.A. in the following year. In a few months' time he went into practice at Ingatestone, in Essex, where he remained for more than eleven years. In 1876 he entered into partnership with Dr. Wyman of Putney. After their dissolution of partnership, which took place this year, he took as partner Mr. John Gay. Although he had not enjoyed good health for some time, the sudden and fatal termination of his illness was unexpected, and the announcement of his death caused great and widespread grief in the places where he was known. Kind, sympathetic, and unsparing in his devotion to his patients, he was much beloved by them. Skilful as a practitioner, his very presence in the sick room inspired confidence, whilst his known uprightness and honourable character made him trusted even in other than medical subjects. In order to mark their appreciation of Mr. Franklin, his patients and friends propose placing a monument to his memory in Putney Cemetery.

JOHN IRVINE, M.R.C.S.

MR. JOHN IRVINE, whose death recently took place at Tarves, was born in 1807. He obtained his professional education at Aberdeen, and in 1828 became a member of the Royal College of Surgeons of England, his examiners for that diploma being John Abernethy, Sir A. Carlisle, and Sir Astley Cooper. He then commenced practice at Tarves, and for many years was one of the leading medical men in the Buchan district. He was one of the oldest members of the Aberdeen Medico-Chirurgical Society, a member of the North of Scotland Medical Association and the Garioch Medical Society, and a member of the original Spalding Club. Mr. Irvine also held a commission as Justice of the Peace, and the respect in which he was held by his medical brethren was shown eight years ago in a complimentary dinner given him on his completing his fiftieth year of practice.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations recently held the following obtained the Fellowship of the College:—

William Berry, Wigan. | Patrick Joseph MacNamara.

THE annual Hospital Sunday collection was made at Bootle on the 13th inst.

AN outbreak of measles has occurred in several towns in North Wales, and the schools in many districts have been closed on account of the epidemic.

ROYAL FREE HOSPITAL.—A concert was given at this hospital on Friday last, Nov. 11th, for the amusement of the patients, under the direction of Mr. O. H. Bamberger. The entertainment was a great success from beginning to end.

THE wife of a working man residing in Birmingham gave birth on the 7th inst. to twin boys, joined together in a most remarkable manner. The infants are reported to be well, but their bodies are so connected that separation would cause instantaneous death.

FATALITY AT A FOOTBALL MATCH.—An inquest was held at St. Helens, on Nov. 15th, on the body of William Edward Taylor, who died from injuries received whilst playing football. The jury returned a verdict that deceased came by his death accidentally.

SANITARY INSTITUTE OF GREAT BRITAIN. — At an examination, held on Nov. 10th and 11th, sixty-two candidates presented themselves—eight as local surveyors, and fifty-four as inspectors of nuisances. Of the former three, and of the latter thirty-one, obtained certificates of competency.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—At a meeting to be held in the rooms of the Medical Society of London on Tuesday, Nov. 22nd, at 4 P.M., Dr. Richardson, F.R.S., will preside and deliver a short address. A paper will be read by Dr. J. J. Ridge on "Alcohol, its Substitutes and Alternatives."

THE steamer *Grosvenor* arrived off Liverpool on the 11th inst., having had fatal cholera on board during her passage from Calcutta. She was allowed to pass the Suez Canal "in strict quarantine." As the result of Dr. Stopford Taylor's inspection she was allowed to enter the dock, and no restrictions were placed on her crew.

ROYAL MEDICAL SOCIETY OF EDINBURGH. — The following have been elected office-bearers:—Presidents: W. A. Turner, M.B., C.M.; G. O. C. Mackness, B.A., M.B., C.M.; H. F. Waterhouse, M.B., C.M., M.R.C.S.; E. H. Ezzard, M.B., C.M. Secretaries: Robert Abernethy and L. A. W. Beck. Chairman of Finance Committee: A. L. Gillespie. Chairman of Library: P. B. Haig. Curator of Museum: F. D. Boyd.

SOCIETY FOR THE STUDY OF INEBRIETY.—Under the auspices of this Society two lectures will be delivered at the rooms of the Medical Society of London: the first on Nov. 23rd, by Dr. George Harley, F.R.S., on the "Action of Moderate Drinking on the Human Constitution; Alcoholic Stimulants as a Bane and Antidote in the Sick Room"; the second on Nov. 30th, by Dr. Norman Kerr, on the "Various Forms which Inebriety may assume."

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a meeting of the members of this Association, on the 11th inst., Dr. Kenyon in the chair, Dr. Barr submitted a plan and section of a new apparatus for the abatement of smoke for factory chimneys. It showed a method of applying the steam jet automatically, and, besides efficiently abating a smoke nuisance, the appliance economised fuel. Dr. Adams read a paper on Outbreaks of Measles, Scarlatina, and Diphtheria in Runcorn. A discussion followed, in which Drs. Vacher, Hope, Welsh, and the chairman took part.

DONATIONS.—At a meeting of the weekly board of the Wolverhampton Hospital, held on Nov. 15th, the chairman (Lieut.-Colonel Thorneycroft) announced that he had received from Mr. W. F. Fryer, of London, the handsome sum of £500 as a donation toward the endowment fund of the institution. A vote of thanks was unanimously accorded to Mr. Fryer for his generous gift.—Mr. Gervas Lennox Tayler has given £50 to the Meath Hospital, Dublin.

Digitized by Google

BEQUESTS.—The late Right Hon. Edward, first Baron de Ramsey, who died on Aug. 9th last, has bequeathed £1000 to the Huntingdon County Hospital, £200 each to the Norfolk and Norwich Hospital, the Hunstanton Convalescent Home, the Royal Hospital for Incurables, Putney, and the Hospital for Consumption, Fulham; and £100 to the Norwich Eye Infirmary.—The late Miss Mary Fothergill of Hensol Castle has bequeathed £500 to the Cardiff Infirmary.

THE HOME FOR INVALID LADIES AT SAN REMO.—Her Imperial Highness the Crown Princess of Germany lately visited the Home for Invalid Ladies at San Remo, of which institution she has been patroness for several years. Her Imperial Highness expressed herself as being much pleased with the arrangements and surroundings of the home, and made some practical and useful suggestions. Dr. Freeman of San Remo had the honour of being presented to the Princess.

FATAL ACCIDENT TO A SURGEON.—A profound sensation has been created in the town and neighbourhood of Wellingborough, Northamptonshire, by a fatal accident to Mr. Arthur D. Gripper, a young surgeon of that place, on Monday evening. About 6 P.M. two working men were going down the walk on the London road, when they met a riderless horse galloping towards the town. Suspecting that something was wrong, they made a search, and found Mr. Gripper lying by the side of the road, unconscious, but moaning. They conveyed him to a neighbouring house, and medical aid was called in. An examination showed that Mr. Gripper had sustained concussion of the brain, and, though every effort was made to save his life, he died before midnight. He had been out on his rounds when he met with his accident, but how it arose cannot be stated with certainty, though he appears to have been dragged a considerable distance with one foot in the stirrup. Deceased, who was a native of Ware, in Hertfordshire, and thirty-two years of age, came to Wellingborough about four years ago as assistant to Dr. Heygate, afterwards entering into partnership with that gentleman. He was very popular with all classes, and his untimely death has cast a gloom over the town. At the inquest on Wednesday a verdict of "Accidental death" was returned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ATTWATER, ARTHUR WILLIAM, L.R.C.P.Ed., M.R.C.S., has been reappointed Medical Officer of Health for the Whickham Urban Sanitary District.

BARST, CHAS. THEODORE UVO, L.R.C.P.Ed., L.R.C.S., has been reappointed Medical Officer of Health for the Howdon Urban Sanitary District, Northumberland.

BROWN, JOHN, L.R.C.P.Lond., L.S.A., has been reappointed Medical Officer of Health for the Bacup Urban Sanitary District.

CADDY, ARNOLD, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the North Lonsdale Hospital, Barrow-in-Furness, Lancashire, vice F. Edge, resigned.

CALDERWOOD, GEORGE, M.D.Univ.Glas., has been reappointed Medical Officer of Health for the Egremont Urban Sanitary District.

COSENS, W. BURROUGH, L.R.C.P. Lond., M.R.C.S., has been appointed House-Surgeon to the Taunton and Somerset County Hospital, vice G. W. Rigden, resigned.

FOWLER, WALTER, M.A., M.B., F.R.C.S.Eng., has been appointed Registrar and Pathologist to the Central London Throat and Ear Hospital, vice G. W. Hill, M.B., resigned.

LUSH, PERCY J. F., M.A., M.B., B.S.Oxon., M.R.C.S., has been appointed House-Surgeon to the West London Hospital.

MONTGOMERY, SAMUEL, L.R.C.P.Ed., L.R.C.S., has been reappointed Medical Officer of Health for the Ovenden Urban Sanitary District.

PATERSON, WM. BROGDON, M.B., C.M.Edin., has been appointed Medical Officer to the Beaufort-street Dispensary, Liverpool.

PIGGOTT, CECIL H., B.A., M.B., B.C. Cantab., M.R.C.S., has been appointed Medical Officer of Health for the Teignmouth Urban and Port Sanitary Districts, vice Lake resigned.

SHELSWELL, WILLIAM ARTHUR, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Hornton District of the Banbury Union, Oxfordshire, vice S. D. MacVicar, L.R.C.P.Ed., L.R.C.S.Ed., resigned.

SMITH, CHARLES CALLOW, M.B. Cantab., M.R.C.S., has been reappointed Medical Officer of Health for the Redditch Urban Sanitary District.

VON WINCKLER, WILLIAM J., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Out-patient Assistant at University College Hospital.

WINSLOW, L. S. FORBES, M.B., LL.M.Camb., D.C.L.Oxon., M.R.C.P. Lond., has been appointed Physician to the North London Hospital for Consumption and Diseases of the Chest.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BOLTON INFIRMARY AND DISPENSARY.—Junior House-Surgeon. Salary £100 per annum, increasing by £10 per annum to £150, with furnished apartments, board, and attendance.

BOSCOMBE PROVIDENT INFIRMARY, Bournemouth. — Resident Medical Officer. Salary £60 per annum, with board and residence.

BURTON-ON-TRENT INFIRMARY. — House-Surgeon. Salary £130 per annum, with a prospect of increase, and rooms, coals, and gas free.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C. House-Surgeon.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Obstetric Physician to Out-patients.

HOME AND INFIRMARY FOR SICK CHILDREN, Lower Sydenham.—Second Honorary Assistant Physician.

PADDINGTON-GREEN CHILDREN'S HOSPITAL.—House-Surgeon. Salary £80 per annum, and rooms.

PARISH OF ST. LEONARD, Shoreditch. — Resident Assistant Medical Officer for the Workhouse and Infirmary. Salary £100 per annum, increasing £10 annually to £120 per annum, with rations, furnished apartments, and washing in the Infirmary.

PEWSEY UNION.—Medical Officer for the Third District. Salary £63 Also for the Fifth District. Salary £40. For each midwifery case £1 will be paid.

ST. GEORGE, HANOVER-SQUARE, PROVIDENT DISPENSARY, Little Grosvenor-street, W.—Residedt Medical Officer. The salary and allowances last year were £235 8s.

STOCKPORT INFIRMARY.—Assistant Medical Officer. Salary £50, with board and lodging.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea.—House-Physician. Honorarium £50 per annum, and board and lodging in the hospital.

WALLASEY DISPENSARY.—House-Surgeon. Salary £120 per annum, with furnished residence, coals, and gas.

Births, Marriages, and Deaths.

BIRTHS.

BATTYE.—On the 12th inst., at Denbigh-street, S.W., the wife of John Howard Battye, M.D., of a son.

CHANING-PEARCE.—On the 8th inst., at Montague House, St. Lawrence-on-Sea, the wife of J. Chaning-Pearce, M.D., of a daughter.

FARNELL.—On the 13th inst., at The Goffs, Eastbourne, the wife of Henry D. Farnell, F.R.C.S., of a son.

MORRIS.—On the 9th inst., at Gordon Lodge, Charlton-road, Blackheath, S.E., the wife of Clarke Morris, M.R.C.S., L.S.A., of twin daughters.

MORSE.—On the 30th ult., at Torrington, N. Devon, the wife of Edward Morse, L.R.C.S., L.R.C.P.Ed., of a son.

POLAND.—On the 11th inst., at St. Thomas's-street, London-bridge, S.E., the wife of John Poland, F.R.C.S., of a son.

RAKE.—On the 25th ult., at Mucurapo, Trinidad, the wife of Beaven Rake, M.D.Lond., J.P., Medical Superintendent of the Trinidad Leper Asylum, of a daughter.

THOMPSON.—On the 7th inst., at Suffolk-place, Sevenoaks, the wife of Herbert Thompson, M.R.C.S., of a daughter.

TWEEDY.—On the 16th inst., at 100, Harley-street, W., the wife of John Tweedy, F.R.C.S.Eng., of a son.

MARRIAGES.

FLIGG—BORTON.—On the 8th ult., at St. George's Cathedral, Grahamstown, South Africa, by the Lord Bishop of the Diocese, assisted by the Rev. Canon Wharton B. Smith, William Fligg, M.B.Edin., son of the late Wm. Fligg, of Scarborough, to Marion Teresa, elder daughter of the late Captain Henry Martin Borton, Royal Artillery.

WALTON—BARTON.—On the 12th inst., at St. Jude's, South Kensington, Arthur Walton, M.S., M.B., to Emily, elder daughter of George Kingston Barton, M.D., F.R.C.S., of Fulbeck, Lincolnshire.

DEATHS.

CARRUTHERS.—On the 3rd inst., at Denbie House, Lockerbie, Dumfriesshire, John Hetherington Carruthers, of Denbie, late Surgeon, Royal Navy, aged 82.

FIRTH.—On the 6th inst., at St. Giles' Plain, Norwich, Eustace Firth, M.D., aged 31.

HUGMAN.—On the 15th inst., at 27, Alma-square, St. John's-wood, William Curtis Hugman, F.R.C.S., late of Guildford-street, Russell-square, after a few days' illness of inflammation of the lungs, in his 73nd year.

MORRIS.—On the 11th inst., at Gordon Lodge, Blackheath, Mabel Annie, aged 2 days, twin daughter of Clarke and Mabel Morris.

SMART.—On the 14th inst., at his residence, 6, Cecil-street, Greenheys, Robert Bath Smart, Surgeon, late of 176, Oxford-road, Manchester, aged 59.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, November 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Ferrier: Some cases in illustration of Cerebral Hemianæsthesia.—Mr. J. Knowsley Thornton: Two cases of Cholecystotomy.

Tuesday, November 22.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. J. Warrington Haward: A case of Excision of a Tubercular Movable Kidney.—Dr. Archibald E. Garrod: A Contribution to the Theory of the Nervous Origin of Rheumatoid Arthritis.

Wednesday, November 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Dr. Herman: On Delivery by the Vagina in Extra-uterine Pregnancy.—Dr. Champneys: On Primary Laparotomy (that is, abdominal section in the latter half of pregnancy, the child being alive) in cases of Extra-uterine Gestation.—Dr. John Williams: A case of Extra-uterine Pregnancy in which Abdominal Section was performed during the life of the Fœtus at the Thirty-fifth Week of Gestation. Specimens bearing on the above subject only will be shown.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Conversazione.

SOCIETY OF ARTS.—8 P.M. Prof. SIlvanus P. Thompson: The Mercurial Air-pump.

HUNTERIAN SOCIETY.—8 P.M. Mr. Fowler: A case of Richter's Hernia.—Dr. Savage: Proposed Lunacy Legislation as affecting Medical Men.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M.—Specimens will be shown by Drs. Edis, G. Granville Bantock, Mansell-Moullin, and others. Mr. J. Bland Sutton: The Nature of the Hymen.—Dr. E. Holland: Electrolysis of Uterine Fibroids.—Dr. Bedford Fenwick: On the Use of Bloodletting in Gynæcological Practice. Council, 8 P.M.

Thursday, November 24.

ST GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, November 25.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Gibbons and Mr. R. W. Parker: Case of Removal of Tumour from the Female Bladder by the Galvano-écraseur, Rapid Dilatation of Urethra, combined with Supra-pubic Incision.—Dr. Clemow: Case of Hysterical Hyperpyrexia.—Dr. Barlow: On a case of Acute Enlargement of the Thyroid Gland.—Mr. R. C. Lucas: The Congenital Absence of an Upper Lateral Incisor Tooth as a Forerunner of Harelip and Cleft Palate (with cases). Living Cases:—Mr. J. H. Makins: A Synovial Cyst in connexion with the Shoulder-joint.—Dr. J. B. Ball: A case of Chorea, with Embolism of a Retinal Artery.

Saturday, November 26.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE Publisher is much obliged to several correspondents for calling his attention to the admission to the advertising columns of THE LANCET of an advertisement which, in so far as this journal is concerned, is of an eminently objectionable character. It was received with others from a very respectable agent in the ordinary way, and by some means escaped critical attention.

VACCINATION WITH CALF LYMPH.

WE lately referred to a case of alleged injury from the use of calf lymph. The father of a child who had been vaccinated at the Animal Vaccine Establishment had written to the *Echo* asserting that his child had suffered from a serious eruption as the result of the operation. This eruption was, however, as we stated, due not to vaccination, but to the administration of bromide of potassium; and we commented on the action of the father in addressing a letter to the public press without mentioning that he had been fully informed of the circumstance that had led to his child's illness. He now writes to us that he does not believe the rash was due to bromide of potassium, because of its limitation to the legs and arms of his child, and because of its prolonged duration. As a result of inquiry, we learn that the child was seen by a number of the medical staff of St. Thomas's Hospital, as well as by the medical officers of the Vaccine Establishment, and that no difference of opinion exists as to the nature of the eruption.

Mr. T. W. J. Allen.—1. Special assistance would be required if no more dissecting were done.—2. Yes.—3. No. They are not on the same footing.—4. Quain's or Gray's Anatomy, Foster or Landois's Physiology, Bell, Nicholson, or Huxley on Comparative Anatomy.

Mr. P. P. Griffith.—The Surgical Aid Society, Salisbury-square, or Surgical Appliance Society, Finsbury-circus.

Mr. Buss (Leominster).—Very shortly.

PHYSICAL EXERCISE FOR A HEMIPLEGIC PATIENT.

To the Editors of THE LANCET.

SIRS,—Perhaps some of your readers know of a tricycle or other machine with mechanism contrived so as to allow pedal and manual exercise for a patient suffering from slight hemiplegia? My object is to enable my patient to have open-air exercise, with the satisfaction accompanying locomotion by his own effort. The principal invalid-chair manufacturers have been communicated with without result.

I remain, Sirs, yours truly,

Aylesbury, Nov. 11th, 1887. R. HARVEY HILLIARD, M.D.

"CHANGE OF AIR."

IN reference to a question on the above subject which appeared in our last issue, we are reminded that the matter is discussed at length in the second chapter of Dr. Lindsay's work on "The Climatic Treatment of Consumption," published by Macmillan.

T. H. S. (Plymouth).—Alchemy, according to Prof. Crum Brown, had its origin in two ancient arts, pharmacy and metallurgy. The pharmaceutical goal was the elixir of life, the "universal medicine," which, if taken *secundum artem*, ensured perfect bodily health for ever. The metallurgic goal was the philosopher's stone, a substance which if mixed with a large quantity of lead turned it into gold.

Sangrado.—Our correspondent might consult Dr. Oscar Jennings' paper on the subject, published in THE LANCET of June 25th last; also Considérations sur le Traitement de la Morphinomanie, Bulletins de l'Académie de Médecine, March, 1887.

Dr. Groom (Wisbech).—We shall be pleased to receive the abstract for consideration.

X. Y. should consult a medical practitioner.

"SEA-SICKNESS."

To the Editors of THE LANCET.

SIRS,—The subject of sea-sickness periodically appears in your correspondence columns, and remedies are recommended and theories advanced as to its causation. No doubt many of the remedies have been proved by practical experience to do good, and we are gainers by being told of them. But it is doubtful if so much can be said of the theories. No theory can be considered a satisfactory one which will not explain why sickness is not, as a rule, caused by horse riding, carriage and railway travelling, swinging, and other jolting or swaying conditions to which the body may be subjected. And a trustworthy theory must explain why custom to the sea gives immunity to sea-sickness, and why some persons never suffer from it. I would suggest yet another theory, which is absolutely useless as suggesting a means of cure or relief. To those who are sceptical as to the relief or curability of sea-sickness this uselessness may, perhaps, be in favour of the theory. It is that giddiness is produced by the unusual motion, and that sickness follows sympathetically, "the stomach sympathising with its dear friend, the brain," as a famous "grinder" used to say. Doubtless, after a time, in some cases, from much vomiting irritability of the stomach is set up, and we have those very severe cases in which the patients are brought to death's door and have to be landed at the nearest port of call to save their lives. On board ship the unusual motion which one cannot, as it were, feel a reason for, though one knows that it is caused by waves; the way in which objects that should be perpendicular are constantly moving out of the perpendicular; the heaving up and subsidence of the deck; and the rolling waters outside—all these conspire to make one giddy. Some people become sick in swings, in trains and carriages, especially with their backs to the engine or horses. The moving ground and surrounding objects in the case of the swing, the flying trees, hedges &c. in travelling—movements all the more odd when one is going backwards—tend to cause giddiness. What giddiness is physiologically, and why some people are more easily made giddy or sick, I cannot pretend to say. Many persons will become sea-sick on board a large steamer who do not suffer in a small boat, or even in a sailing ship. It is possible that the mind is better able to realise the surroundings and "the reason why" of the motion in the smaller vessels than in the huge steamer, which, apparently, ought to be immovable, but is not. No doubt, to a person whose head is beginning "to go round," the smells common to steamers may give the *coup-de-grâce* and make him sick, when otherwise he might have escaped with a feeling of giddiness and discomfort. I would therefore suggest that in the case of those who get over sea-sickness custom cures the giddiness caused by the unwonted motion; while those who never suffer from sea-sickness are endowed with unsympathetic stomachs, or are not easily made giddy. Most persons who escape sea-sickness suffer from a feeling of giddiness and discomfort for the first day on board ship. My excuse for now speaking of myself is that I am one of the lucky few who escape sea-sickness, and my immunity has been proved by many voyages. I have generally suffered from an uncomfortable giddy feeling for the first day on large ocean steamers; once in a high-sided surf boat, from which I could see nothing but sky and distant sea; in this latter case the sky and the horizon and the boat heaved up and down in a most unintelligible manner, and made me very giddy.

A not uncommon symptom among those who are going to be sea-sick is an uncomfortable feeling, or even pain, in the perineum; this I have felt in a swing. Those whose imaginations make them sea-sick on board a vessel moored in smooth water do not, I think, form evidence against this theory of giddiness, for every medical man has had equal proof of what imagination can do.

I am, Sirs, yours faithfully,

Oct. 19th, 1887. VERTIGO.

EXHIBITIONS IN EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—Allow me to supply an omission in my letter of last week. All applications relating to the examinations for these exhibitions must be sent in on or before December 1st.—Yours faithfully,

Reigate, November, 1887. C. HOLMAN, M.D., Treasurer.

A JUDGE'S RESPECT FOR MEDICAL SERVICES.

WITH reference to the want of appreciation of the value of medical men's services displayed by Belgian courts of justice a story is related by a correspondent of a Belgian medical journal of a provincial judge whose decisions were habitually in favour of patients who disputed their doctors' bills and of quacks who infringed on doctors' practices. A time came when sickness invaded the judge's house, and he was obliged to have the doctor—or, rather, a succession of doctors, for he went from one to another till he had called in nearly all the local members of the profession—constantly in the house. These all demanded a fee of ten francs at every visit. The judge's purse not being a long one, he was terribly distressed, and at last applied to an old friend who was a medical man, practising, however, at a distance. This friend made inquiries amongst his professional brethren, and found that the local medical association had passed a resolution that the judge should be taught a little more respect for medical services by being charged ten francs a visit—not, as it would seem to us in this country, a very exorbitant fee for a man in the position of a county-court judge to be expected to pay.

Surgeon J. E. Wask, M.S.—We understand that Mr. Pepper will deliver an address before the Metropolitan Branch of the British Medical Association in the early part of 1888, on "Medical Witnesses—their Duties and Remuneration"; and that this will be published in pamphlet form, with a reprint from THE LANCET of his lectures on "Practical Legal Medicine."

A Subscriber.—We cannot give our correspondent further information than that contained in our advertising columns.

F. M.—We are not aware that the article has appeared in print.

Mrs. I. White.—We are unable to accept the offer.

Dr. W. P. Watson.—We cannot exchange.

LARYNGEAL SPASM WITH ASSOCIATED NERVE SYMPTOMS.

To the Editors of THE LANCET.

SIRS,—Being somewhat at a loss to know how to continue the treatment in the undermentioned interesting case, I should esteem it a great favour if any of the readers of your valuable journal could advise me what to try, and who have found benefit, especially if permanent, to their patients, as the one I am treating is too frequently still a sufferer from these peculiar attacks.

The patient is a healthy, robust-looking woman, aged twenty-five, the mother of two children. She was married at the age of twenty, and, except for these attacks, enjoys excellent health. Since the age of sixteen she has been at varying, though frequent, intervals suddenly seized, usually after meals, with considerable difficulty in breathing, almost amounting to imminent asphyxia, this being associated with a sucking sound. At the same time urticaria rapidly developed itself, often from head to foot, with intense irritation, whilst her features are greatly distorted. She does not lose consciousness, nor altogether the power of speech. The pulse is quickened and small, the breathing being laboured and also quickened. Vomiting sometimes supervenes, giving the patient more or less speedy relief. Otherwise it generally takes, according to the severity of the attack, from twenty minutes to half an hour to recover the breathing. I have tried the following remedies with marked benefit, but still not with, as yet, any permanent relief:—Anti-dyspeptics, nux vomica, bromide of potassium, arsenic, and general tonics; and at the time of attacks ether, chloroform, hot sponges to the throat, ozone papers, and stimulants.

I am, Sirs, yours very truly,

Nov. 15th, 1887. M.B.

WATER-TIGHT CASES.

To the Editors of THE LANCET.

SIRS,—If Messrs. Mayer and Co. had taken the trouble to read the description of our "Patent Water-tight Cases," it would have saved your valuable space and our time in replying to the letter which appeared in your issue of the 12th inst. What we principally claim is not the metal grove or tongue, but the covering of porpoise hide, thereby rendering the case impervious to moisture (the groove, or tongue, is likewise covered with the same material). Messrs. Mayer and Co.'s verdict of superiority is somewhat premature. Considering they have never seen one of our cases, we fail to see how their verdict has been arrived at.

We are, Sirs, your obedient servants,

London, Nov. 15th, 1887. ARNOLD AND SONS.

STROPHANTHUS.

To the Editors of THE LANCET.

SIRS,—As specimen pods of a species of strophanthus different from that which is in general use are being offered to the medical profession and to materia medica museums, we beg to say that having on hand about 10 lb. of pods of the genuine drug as now employed in medicine we shall be happy to present a specimen for any museum of materia medica or to any medical man who may write for the same. We are also willing to supply, without charge, seed or tincture for experimental purposes to any physician or institution desiring the same.

We are, Sirs, yours very respectfully,

BURROUGHS, WELLCOME, AND CO.

Snow-hill-buildings, E.C., Nov. 10th, 1887.

A CORONER'S INQUEST IN THE COUNTRY.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert this letter in your valuable journal, showing what a farce a coroner's inquest may be, and hoping something may be done to rectify the matter by making it publicly known in the medical press, since it has failed in the daily newspapers.

On Thursday last (Nov. 4th) I was called to see J. G——, a lad of eighteen years of age, who was a farm servant. When I arrived at the farm (7 A.M.) I found the patient dead. It appears he had not felt well for some days previously, but had not sought medical advice, and he did his work as usual on Wednesday. On calling him to get up in the morning he made no response, whereupon they opened the door of his room and found him in a dying condition in bed. A messenger was sent off at once for my principal, who despatched me. An inquest was held next day, but I have not heard the verdict of the jurymen, neither did I receive any intimation from the coroner to make a post-mortem examination or to attend the inquest. I am told it is not the first case by any means that has happened in this manner, and the coroner is no doubt complimented in the way in which he cuts down the expenses. Is this justice? I enclose my card, trusting that I have not trespassed too much on your space.

Believe me, Sirs, yours sincerely,

Nov. 8th, 1887. JUSTITIA.

STRUMOUS ULCERS.

To the Editors of THE LANCET.

SIRS,—If any of the profession could suggest anything for the following case I would be much indebted to them. I have at present under my care a girl, about nineteen years of age, who is in good health, except that all round her neck, chin, and both sides of her face she has large scrofulous sores, and all the lymphatic glands of those parts are enlarged, and in many places undergoing caseous degeneration. The glands at the base of the ulcers have been scraped, and after that, under dressing of red wash, they healed. But they will not keep healed. As soon as an ulcer has healed the scar will keep all right for two days. Then a few minute yellow pustules appear here and there upon it. If these are pinched, a little unhealthy fluid escapes and dries into a scab, beneath which unhealthy ulceration rapidly goes on. If they are left alone, the pustules rapidly enlarge and burst, the fluid dries into scabs, beneath which ulceration rapidly goes on, and coalesce with others, until the whole scar is broken down again. Under proper dressing the ulcer will again heal, to again break down in the same way. This goes on week after week, and month after month, in spite of the greatest care, the most careful dressing, and the most varied treatment, both internally and externally.

I am, Sirs, faithfully yours,

November 14th, 1887. M.B.

WHAT MUSCLES ACCOUNT FOR IT?

To the Editors of THE LANCET.

SIRS,—I would like the opinion of some of your physiological readers on the following facts.

My paternal grandfather, who died at eighty-eight, had all his life the power to eject food or fluid from the stomach at will, at any time. My father, who is eighty-one, always had the same gift. So have I, who am forty-nine. When a medical student I have—stupidly, I admit—often swallowed for a wager large doses of narcotic poisons diluted in water, merely retiring for a few seconds immediately after. There is not the slightest difficulty in the act, and, of course, no nausea. I frequently wash out my stomach in the morning with two or three successive tumblerfuls of cold water, and feel fresher after it; and if at any time troubled with acidity, dilution and ejection are naturally suggested. Now, what voluntary muscles account for this? Could not physiological experiments be made on the Beaumont principle? Not that I want to go in for them; but there must be many similar cases.

I am, Sirs, yours truly,

Nov. 9th, 1887. M.D., C.M.

THE LANGMORE DEFENCE FUND.

THE Secretary of the above fund, Mr. G. Hastes, acknowledges the receipt of one guinea, sent by Surgeon-Major Stanley L. Dobie, 4th Madras Cavalry, Kamptee, India.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Coats, Glasgow; Sir J. Paget, London; Mr. W. Whitehead, Manchester; Dr. Whittle, Brighton; Mr. C. S. Rose, London; Mr. C. Mackie, Port Glasgow; Mr. T. Holmes, London; Dr. Voight, Southport; Mr. E. Clarke, London; Dr. Moir, St. Andrews; Mr. F. G. Smith, Liverpool; Dr. Lucas, Gibraltar; Mr. Wilkinson, Birkenhead; Dr. Oscar Jennings, Paris; Mr. A. E. Taylor; Dr. McCaw, Belfast; Drs. Silk and Goodhart, London; Mr. C. E. Jones, Watford; Dr. Finlayson; Dr. Groom, Wisbech; Dr. Hilliard, Aylesbury; Messrs. Burroughs and Wellcome, London; Mr. E. Casse, Bournemouth; Messrs. Barnes and Co., New York; Dr. Abraham, London; Mr. Heale; Dr. Holmes, Southam; Dr. Sansom, London; Dr. Whitla, Belfast; Mr. Borham, Fulham; Mr. Raven, Broadstairs; Dr. Cheadle, London; Dr. G. Thompson, Stapleton; Messrs. Warren, Bristol; Messrs. Tillotson and Son, Bolton; Mr. G. Kelly, London; Mr. Maw, Bradford; Mr. Van Praagh, London; Dr. Stallard, Manchester; Messrs. Faulkner and Co., Manchester; Dr. Branthwaith, Rickmansworth; Messrs. W. and A. K. Johnston, Edinburgh; Mr. Brown, Brompton; Messrs. Lee and Nightingale, Liverpool; Mr. Andrew, Stockport; Messrs. The Bowman Lecture

ON THE

RELATION OF OPHTHALMIC DISEASE TO CERTAIN NORMAL AND PATHOLOGICAL CONDITIONS OF THE SEXUAL ORGANS.

Delivered at the Ophthalmological Society, Nov. 11th, 1887,

BY HENRY POWER, M.B. LOND., F.R.C.S.

MR. PRESIDENT,—Allow me in the first place to thank you, Sir, and the Council of the Ophthalmological Society for the distinguished honour conferred upon me in entrusting to my hands the "Bowman Lecture" for the present year. No one can, I think, occupy the position I now hold without a feeling of trepidation at the task he has undertaken—the task of placing before a Society of experts the results of some of his own observations on subjects with which they are as familiar as himself, and regarding which it is as difficult to make general statements which shall not be platitudes as to adduce special cases which shall not be tedious, uninteresting, and uninstructive. With the multitude of observers in every civilised country who with the best appliances are now engaged in the practice of ophthalmic medicine and surgery, few indeed can hope to present to his brethren any anatomical description that shall compare with the short but pregnant chapters on the parts concerned in the operation on the eye by the distinguished surgeon after whom this lecture is named, any new instrument approaching in value the ophthalmoscope, any mode of treatment approximating in importance the application of cylindrical glasses for certain errors of refraction, or who can indicate and support by reference to numerous carefully collected cases the relations that exist between certain affections of the eye and such a specific constitutional disease as syphilis. I feel that I must at least be contented with a humbler *rôle*, and I have ventured to take as my theme the relations of the diseases of the eye to the normal and pathological conditions of the sexual organs—a subject which, although discussed in several monographs, is only briefly referred to in modern text-books, and yet which seems to present many points of interest.

The generative system, developed essentially from the mesoblastic layer of the embryo, remains undeveloped, with its function in abeyance, to the age of thirteen or fourteen years in girls and of fourteen or sixteen years in boys, though, of course, slow maturation of the spermatoblasts in the one sex and of the primordial ova in the other is taking place from birth to puberty. During infancy and childhood no influence of the sexual system on affections of the eye can be demonstrated, nor can any difference be shown to exist in this respect between boys and girls. After this period, however, the changes induced in the economy by the development of the sexual organs exert a powerful influence on the forms presented by ophthalmic diseases in general and give rise to marked contrasts in the affections of the eye in the two sexes. Hence it will be well to make a primary division of the subject into the relations of the sexual organs to the eye in males and females respectively, and then to follow, so far as practicable, the forms of disease which occur at different periods of life and different conditions of the system.

The influence of the sexual system upon the eye in man is far less potent, and the connexion is consequently far less easy to trace, than in woman. No doubt even moderate sexual indulgence exhausts the physical powers: "Omne animal post coitu triste est," says the old adage; and if the indulgence be extreme various troubles to which I shall presently refer are experienced; but in young unmarried and continent men the customary rare and spontaneous emissions of semen, which are the correlatives of the menstrual discharge in women, have no perceptible effect upon the general health, and far less upon the structure or function of the eye. In women, on the other hand, the sexual system, in accordance with its more complex structure, its larger bulk, and much greater nervous and vascular supply, together with its wider sympathies, is much more profound. That this circumstance did not escape the observation of the older physicians is sufficiently attested by the remark of Hippocrates—"Propter uterum mulier tota est morbus"; or that of v. Helmont—"Propter solum uterum mulier est quod est." It is, indeed, one of the arguments against the higher education of women that, with some remarkable exceptions, the normal performance of the act of menstruation tells on the economy, rendering even very strong women less capable of mental and physical exertion, owing to pain, languor, and diarrhœa; whilst the defective, excessive, or difficult and irregular discharge of the function is constantly followed by derangement of some part of the organism, and not unfrequently of the eye. And if this be true of the detachment of the unimpregnated ovum, how much deeper and more important an influence must be the effect of that great effort of the system by which a new creature is generated, nourished, and cast forth by the immensely developed pregnant uterus.

The supervention of puberty in boys is attended with rapid growth of the body in height and weight, and in some instances, though not always, with increased mental activity. I say in some instances, because not unfrequently the rapidly growing boy is dull and languid, and really requires protracted sleep—a point too much neglected by parents and schoolmasters. The practice of masturbation at this period has been considered by many observers to be a fertile source of ophthalmic trouble. The effects have been particularly discussed by Cohn,[1] Boggs,[2] Fitzgerald,[3] Mooren,[4] and Hutchinson.[5] The principal symptoms noticed by these authors are of a functional character. Thus, Cohn's cases indicated retinal irritation. They were seven in number, of whom four were boys, and the chief symptoms he noticed were photopsiæ, muscæ, and muscular asthenopia. The vision was not in any instance deteriorated; it was of normal acuteness in all. The photopsiæ that were complained of consisted in the appearance of stars, and bright, sometimes coloured, dots, rings, snowflakes, and the like, and an unpleasant dazzling. Hutchinson observed, in addition to similar symptoms, that the patients complained of stiffness and peculiar sensations about the lids. Examination with the ophthalmoscope affords little or no information. The media may be perfectly clear, and the disc, retinal vessels, retina, and choroid present no indications of disease. The symptoms seem to be essentially dependent on anæmia and nervous exhaustion, or at least upon conditions of disturbed circulation in the retina and visual centres.

Several inflammatory or subinflammatory symptoms have been noticed by different authors. Thus, Förster and Cohn both maintain that there is a connexion between persistent conjunctival inflammation and masturbation, and they adduce cases in which hyperæmia, follicular and catarrhal inflammation, and even trachomatous infiltration of the conjunctiva, resulted, or appeared to result, from the habit. The evidence on which reliance was placed that these affections were due to masturbation, was that masturbation was practised, that the inflammation was persistent and intractable under ordinary treatment, and that when the habit was discontinued the ophthalmic disease subsided and ultimately disappeared.

Both Michel and Cohn have noticed blepharospasm. They admit, however, that the evidence was not very satisfactory; for although many cases of blepharospasm occurred in which it was also stated in the notes that "excessive onanism" was practised, yet there was no evidence of improvement when the habit was given up. It must not be forgotten that blepharospasm is a common accompaniment of errors of refraction, and that any circumstance which would tend to weaken the bodily powers would intensify the symptoms arising from such defect. Moreover, there are other general states of the body which might be the efficient cause of the spasm, the exclusion of which in any given case would require a much more exhaustive examination than is given in the histories of these cases. Cohn

states that the subjects were mostly boys or young men from eight to twenty years of age, who appeared delicate. In most instances the spasm affected both eyes, though occasionally only one was attacked.

In the paper read before this Society by Dr. Fitzgerald, and printed in the Transactions, he has given an account of the results of masturbation in three young ladies. In one of these there was intense neuro-retinitis of one eye; in the second, with hysterical symptoms, there were at first no ophthalmoscopic signs beyond slight haziness and pallor of the optic discs, but white atrophy of both discs subsequently occurred; and the third presented hyperæmia of the disc with asthenopic symptoms. In the first case visual acuteness in the affected eye was reduced to counting fingers, but with restitution of the menses recovery rapidly followed. In the second case total blindness resulted. It will be noted that the physical lesions, as well as the impairment of vision, were greater in Dr. Fitzgerald's than in Cohn's cases, but Dr. Fitzgerald himself admits that his second case, which terminated in white atrophy, might have arisen from some other cause.

I may mention that I have seen one case of a rare disease, agoraphobia (or dread of open spaces), in a man aged thirty-two, who himself attributed it to extreme nervousness engendered by excessive masturbation in youth. He could live in comfort in towns, and was happy in crowded streets. The presence of lofty buildings removed all his anxiety, but in the country, and especially in an open plain, he was overcome with fear and apprehension, and life was a burden to him. There was in this case a considerable degree of amblyopia, vision being reduced to $\frac{1}{100}$ths. The attacks of agoraphobia were irregular in their occurrence and in their duration. He complained of seeing numerous muscæ, some bright, like diamonds, and some dark, like smuts. He was myopic, and used −4·5 D., but there was no apparent disease of the fundi.

Upon the whole, I am inclined to think the effects of masturbation have been exaggerated. No doubt when self-abuse is frequently practised—and cases are given where it was repeated several times daily—harm may result, and possibly even white atrophy of the discs be produced; but we may be sure that such cases are very rare; and it is to be remembered that the glands are active in youth, their activity being, in fact, the stimulus to the vice, whilst any injurious influence is probably first evident in loss of accommodation and the usual symptoms of accommodative and muscular asthenopia, a symptom that alarms the patient, and is likely to lead him to discontinue the habit before any permanent harm is done to the system or eye. I have found (and others, I have no doubt, have also found) that it is difficult to institute any inquiries in this direction. If the lad is young and pure-minded—and let us hope there are many such in England—one feels that it is injudicious to suggest what may be unknown; and, on the other hand, if the boy be naturally vicious, it is probable he will not hesitate to lie. In the few cases in which, from special circumstances, I have arrived at the conclusion that self-abuse was practised, or respecting which I have received some hints from parents, or have been told outright by the patient himself, no serious or permanent injury to the eye seemed to me to have resulted. The condition was rather fear of what might happen, perhaps induced by reading the pamphlets of quacks and charlatans, than that any disease had been produced. In the case of girls, I must frankly admit that it seems to me impossible to ask any questions on the subject at all, and I have not even dared to interrogate the mother. If it is difficult to institute inquiries upon this point, there is, I think, a mode of treating it which commends itself to my mind as being both simple and successful, whilst it can be equally applied to either sex. It consists in directing that on retiring to rest the arms should be kept outside the bedclothes. In cold weather a jersey may be worn. This plan, with due attention to physical exercise, the relief of constipation, and the avoidance of too great mental excitement, has, I know, been successful in some cases.

At the age of puberty, or a little later in boys, I have seen cases of hæmorrhage on the retina the cause of which was very obscure, but which I was disposed to attribute to constipation of the bowels—a condition that may itself result from masturbation. One such case I showed to the Society a year or two ago, in which no renal trouble could be discovered, yet in which there were numerous hæmorrhagic and white patches, which have yet not wholly disappeared. Through the kindness of Dr. Mackinlay I have this very day seen a case of hæmorrhage upon or in the retina, and large flocculi in the vitreous of a lad of nineteen years of age, thin and ill developed, who, whilst admitting frequent masturbation, presented good teeth, healthy urine, and general freedom from disease, whilst refraction was hypermetropic.

I do not propose to enter into any detailed account of the effects upon the eye of such morbid conditions of the sexual organs in either sex, as gonorrhœa and syphilis, since their consideration would open up a field far too wide to receive adequate treatment within the limits of an hour's lecture; but I would point out that these conditions are frequently initiated between the ages of eighteen and twenty-five, the results of such inoculation leading at first to iritis and its consequences, but often affecting that organ secondarily by inducing some slowly progressive disease, such as locomotor ataxy or some other serious nervous affection. The sad results of many of these cases constitutes one of the most cogent arguments for the re-enactment of the Contagious Diseases Acts, the abolition of which in deference to ignorant and senseless popular clamour all practitioners must deeply deplore. How beneficial they were I may be allowed to state from my own experience at Chatham, which I am sure will be endorsed by the thoroughly practical and highly intelligent house-surgeon of St. Bartholomew's Hospital, Chatham, Mr. Nankivell. When I first attended that hospital some fifteen years ago syphilitic affections of the eye were common; the Acts were passed, and for several years diseases of the eye dependent upon syphilis all but vanished; the Acts were repealed and they reappeared, and Mr. Hartridge, who now holds the post of honorary ophthalmic surgeon to that hospital, assures me they are now common.

Of the disorders of vision which are attributed by the patient of youthful or middle age to sexual excess, both legitimate and illegitimate, amblyopia, the appearance of muscæ, and loss of accommodation are the most common. Of such excesses I suppose most of us have heard revolting details enough. But occasionally more serious results may follow. I saw one case of great pallor of the optic disc in an officer home on leave from India, in whom I am inclined to think the condition of the discs, with the great impairment of vision that accompanied them, were produced by six weeks' sedulous devotion to the pleasures and vices of London life. I was assured in that case that he had led a life of perfect continence for several years in a remote country district in India, and that his vision had on his arrival in this country been perfect. In that instance vision recovered its normal sharpness when the cause of the impairment was pointed out and removed, though the discs remained pale.

The departure of sexual power is so gradual in men that it is hard to indicate any relations between its loss and ophthalmic disease. I have, however, occasionally seen cases of widowers who complained of anomalous symptoms, such as pain in and around the eyes, and confusion of vision, which they attributed, perhaps rightly, to sudden and prolonged suppression of accustomed seminal discharges. I have certainly seen cases of white atrophy of the optic discs in old men who had been indiscreet enough to marry young and prepossessing women. Perhaps previously existing disease in these cases was aggravated by the proceeding. Tissot gives a case (and others are quoted by Hoffman of an analogous kind) in which a man aged fifty-nine, three weeks after marrying a young woman, became suddenly blind, and died in four months.

Turning now to the opposite sex, it may be remarked, in the first place, that the great changes occurring in the whole system of a woman at the period of the establishment of the catamenia are not likely, as I have pointed out, to be without their influence on the eye. The experiments of Röhrig have demonstrated the effects that are obtained by electrical stimulation of the ovaries, such stimulation in the rabbit causing a rise of blood-pressure from 12 mm. to 24 mm. of mercury. And we accordingly find that several conditions of disorder or disease of the eyes are met with at this period, whilst functional disturbance of the act of menstruation is constantly a source of visual trouble. At this time, under normal and healthy conditions, the process of growth and development are more rapid and vigorous that at any other period of life. The appetite is increased; much more work is thrown upon the digestive organs; assimilation is at its height; the quantity of blood and the activity of the circulation are augmented; the excitability of the nervous

Digitized by Google

system, as manifested by the exaltation of the emotional activity, is greatly increased; there is a tendency to local congestion of different organs before the uterus accepts its function, which is exhibited by diarrhœa, headaches, or abdominal pains, which at length culminate in and become restricted to the menstrual discharge. It is not surprising, then, that when any circumstance interferes with the institution of the function, the close and extensive plexus of the choroidal vessels becomes surcharged with blood, and that occasionally one or more of these should give way, permitting their contents to escape into the vitreous humour. In such cases the patient, after some premonitory symptoms—as headache, vertigo, fainting, inability to exert the mind,—complains of sudden impairment of vision. This is often at first slight, and either no change may be perceived with the ophthalmoscope, or the alteration may only reveal itself by some slight haziness to the observer, or by the presence of muscæ and lines or webs to the patient; but after one or two ineffective returns of the effort to menstruate, a more copious effusion may take place, rendering the media so obscure that the details of the fundus are wholly unrecognisable, a dim reflex being alone perceptible. In some cases, perhaps in most, this may clear up, and vision by degrees, and after the lapse of a considerable period, become normal; but I have seen several instances where the eye has never regained its former visual power. Cases of choroiditis analogous to those to which I have just referred may be found in many treatises, and an examination of them will show that the congestion and effusion or inflammation sometimes affects the anterior region of the choroid, sometimes the posterior; that it may be circumscribed and small in extent, or diffused, and affecting apparently the whole membrane; that it may be accompanied by actual hæmorrhage, or that there may be effusion of lymph only; and that it may terminate either in perfect recovery or with some deterioration of vision, which may be general or limited to a certain area of the field, or, lastly, in loss of vision with white atrophy of the optic disc. The effusion that takes place in these cases is probably in most instances of the nature of lymph; at least, the reflex is dark and not ruddy in tint; but now and again actual blood is poured out, and I exhibited to the members of this Society two years ago a healthy and apparently well-developed girl in whom a large clot of blood of crimson colour was visible immediately behind the lower segment of the iris. This presented the extraordinary feature that whilst undergoing little change in its form or size it retained its colour unaltered for more than a year, and only slowly disappeared by diffusing itself into the substance of the vitreous. I may just add to my former account of the case the fact that the eye now presents normal aspect, and that the vision is $\frac{6}{9}$ in the affected eye. A very similar case of hæmorrhage into the vitreous in a girl of fourteen, which took place prior to the establishment of menstruation is recorded by Oursel. M. Dor[6] also gives the case of a girl in whom the catamenia had not yet appeared, but who presented hæmorrhages in each vitreous, the blood disappearing and reappearing at intervals. When menstruation at length supervened with regularity, the hæmorrhages and the amblyopia which invariably accompanied them disappeared and did not again return. Occasional hæmorrhages into the parts surrounding the eyes occurring at a later period of life in cases of amenorrhœa and of dysmenorrhœa have been placed on record. Fritz gives a table compiled by Puech, from which it appears that in 200 cases of disturbance of the menstrual function there were ten cases of hæmorrhage from the lids and caruncle.

Amongst the affections which are believed by some observers to be associated with amenorrhœa, phlyctenular ophthalmia may first be mentioned; but it may reasonably be questioned whether it is a direct or an indirect effect of menstrual disturbance. The difficulty which leads one to reject many cases that seem at first sight to be supported by clear evidence is the difficulty by which we are so frequently confronted, the concurrence of several causes, amongst which it is difficult to select the efficient one. A woman may be amenorrhœic or may suffer from dysmenorrhœa, and the eyes may present such affections as keratitis, choroiditis, or optic neuritis; but it does not follow that either of these diseases is the direct consequence of the amenorrhœa or dysmenorrhœa. It may result from dental disease or from intestinal irritation, or may be the consequence of some affection of the nervous centres; or, as Mr. Habershon laboured to prove at our last meeting, there may be strong hereditary predisposition to ophthalmic disease, which, though latent, is ready to develop on slight provocation. A case cited by M. Oursel, which he regards as typical, is that of a young girl with a good family history, who was accustomed to suffer at her menstrual periods severe neuralgic pain in the face. At about the age of sixteen she was subjected to violent emotional excitement, and as a result suffered from amenorrhœa, with much pain, nausea, and vomiting, and phlyctenulæ appeared on one eye, and from this time forth for six months or more pustules formed at the period when the catamenia should have occurred, sometimes on the right, sometimes on the left eye. After an unusually severe attack the girl applied to M. Courserant for relief. Bitter tonics, friction of the skin, revulsives to the lower extremities, fumigations of the vagina with aromatic plants, and the administration of aloetic purges re-established the menstrual flow, and with the recurrence of this discharge the phlyctenulæ ceased to appear. This, no doubt, is a fairly typical case, and the eye symptoms may reasonably be regarded as directly connected with the amenorrhœa; still, it may just be pointed out that no mention is made of the condition of the teeth, or of the presence of irritation or disease of the intestinal mucous membrane, or of the state of the heart and other organs, though it is possible that all these may have been investigated and sources of trouble excluded.

Mooren finds diseases of the sclerotic, and especially episcleritis, to be more common in women than in men, and thinks that it is associated with menstrual disturbance. I consider episcleritis to be a rheumatic affection, and believe that it is generated by exposure to wet and cold in a state of exhaustion, and can quite believe that it is more likely to be induced, or, if present, for the symptoms to be exaggerated, when the system is enfeebled by the presence of the catamenia, but should hesitate to accept uterine disease as anything more than a predisposing cause of its occurrence.

An exceedingly interesting *résumé* of the affections of the cornea, and especially of interstitial keratitis, in regard to sex and age, has been drawn up for me by Mr. Andrew E. Wynter, from the ward books of the ophthalmic department of St. Bartholomew's Hospital. I cannot express the results better than he has done:—

Number of Cases of all kinds of Keratitis in Males and Females at different ages.

Age.	Male.	Female.	Proportional decimal.	
			Male.	Female.
— to 10	42	77	0·304	0·37
11 to 20*	37	73	0·265	0·356
21 to 40	39	39	0·28	0·19
41 to 50†	9	5	0·067	0·024
50 to —	11	11	0·08	0·053
Total	138	205		

* Menstruation commencing. † Climacteric.

The table shows that: 1. There are many more cases (205 females to 138 males) of keratitis occuring in females than males. 2. That the difference is most marked in the decade previous to and contemporaneous with the decade of commencing menstruation (150 females to 79 males). 3. That in the first decade 30 per cent. males to 37 per cent. females of the whole number occur. 4. That in the decade of commencing menstruation there is a distinct difference in the percentage of males and females; thus in males it is only 26 per cent., while in females it is 35 per cent., an increase of nearly 10 per cent., due to, or certainly contemporaneous with, the period of commencing menstruation. 5. That during the menstrual period of life (twenty to forty) there is a diminution among females compared with the same time of life in males. Thus in females 19 per cent. occur between the ages of twenty to forty years, as against 28 per cent. for the

[6] Galezowski's Recueil, 1884, p, 164.

Digitized by Google

same period in males. 6. That at the age of the climacteric (from forty-one to fifty) there is a sudden fall in the percentage, the males being higher (6·7 per cent.), the females being 2·4 per cent. After fifty there is a rise in the number of cases in both sexes, males being still greater. Thus: males, 8 per cent.; females, 5·3 per cent. 7. That it is curious to note the fact that, in spite of the greater exposure &c. in males, the female cases have a greater sum total, suggesting that women are more liable to keratitis than men. 8. In some cases occurring between twenty to forty years in women, over-lactation or bad confinements have been given as the constitutional causes.

An examination of our ward books further shows that interstitial keratitis is more frequent in women than men, omitting cases of keratitis punctata, traumatism, and keratitis due to (*a*) granular lids, (*b*) mercurial poisoning, and (*c*) lesions of the fifth nerve, the chief difference lying at about the on-come of menstruation (i.e., ten to twenty), 28 females to 13 males. 2. That the average age for men to be attacked with interstitial keratitis is $17\frac{6}{75}$ years, whilst the average age for women is $15\frac{8}{13}$ years. So that women are attacked a year and a half earlier, the average being brought down by the great number occurring about the supervention of menstruation. 3. No cases occurred at the climacteric.

Galezowski[7] and Daguenet[8] have recorded several cases of disease of the cornea resulting from sudden suppression of the menses. The patient in M. Daguenet's case was thirty-seven years of age, married, but childless. Whilst in perfect health she was exposed to cold in washing linen in the month of January. Suppression of the menses followed, and in the course of the night she was awakened by intense pain in the left eye. The whole left globe was inflamed, and a large abscess formed in the substance of the cornea followed by leucomata, which, however, cleared up sufficiently to enable the patient to pursue her avocation.

Mooren gives the case of a girl of fourteen who had an intense keratitis pannosa, and who, notwithstanding the fact that every symptom of her molimina menstrualia was present, could not be brought to menstruate; yet a recurrence of the inflammation occurred every four weeks, and treatment continued for a year proved entirely ineffectual. When menstruation did occur, a sudden change took place; but the tissue of the right cornea was so altered that, although it remained transparent, it became conical. I entertain no doubt that the age of puberty in girls, and probably in boys also, is one in which interstitial inflammation of the cornea is particularly apt to occur, and at that period in delicate children suffering from inherited syphilis the attack may be extremely severe. I remember one case in particular of a girl of fourteen, in whom menstration had just commenced, and who was exposed to cold and a somewhat spare diet. The cornea, after becoming cloudy, was invaded by vessels which were so numerous, that only perception of light remained in the eyes. I despaired of the recovery of vision, and she began to learn the alphabet for the blind. With the establishment of the menses, however, improvement commenced, and by degrees, with appropriate treatment, vision was absolutely and perfectly restored. Thaon[9] also points out that interstitial keratitis may be coincident with the supervention of menstruation. Mooren,[10] on the other hand, gives a good case of double interstitial keratitis, in which the symptoms greatly increased in intensity during the menstrual period.

Iritis of a serous type, affecting sometimes one, sometimes both eyes, has been described by many writers as a concomitant of amenorrhœa and of dysmenorrhœa. The causes of the uterine trouble have been very various: mental shocks and worry, and sudden exposure to cold, are amongst the most common; and the results have been sometimes satisfactory, sometimes serious.[11]

In Thaon's case amenorrhœa was suddenly occasioned by grief at the loss of a child. Some pain in the eyes was felt. There appears to have been choroiditis, for the vitreous contained flocculi. With re-establishment of the menses recovery of vision took place, only some slight synechiæ posteriores being left. In M. Levat's case recurrent attacks of serous iritis occurred with each return of the menses, which had been suppressed by a violent mental shock. Improvement resulted from treatment. In Kay's case the menses were irregular and an attack of serous iritis accompanied their return. In this instance appropriate treatment effected a cure. In one of M. Oursel's cases the patient, aged nineteen, was very irregular, and both eyes were affected; a glaucomatous attack supervened. The patient declined operative treatment. In another case of Oursel's double iritis supervened upon a menstrual period, synechiæ formed, and the case was complicated with keratitis and hæmorrhage into the anterior chamber. Wecker, Caudron, and others have reported cases of double irido-choroiditis, which certainly followed, and apparently resulted from sudden suppression of the menses.

Retinal apoplexy consequent on sudden suppression of the menses has been described by several writers. Thus, Léon Oursel[12] gives the case of a previously healthy woman who, while menstruating, was caught in a violent shower of rain. Sudden arrest of the function occurred, followed by rigors, headache, and vomiting. Two days afterwards she discovered suddenly that the vision of the right eye was almost lost. Ophthalmoscopic examination showed that there was a large retinal hæmorrhage covering the macula lutea. In this case almost complete recovery, with only a faint central scotoma, resulted. A similar case is recorded by Danthon.

I saw, with Dr. Gill, a young lady twenty-two years of age, who two years previously had swum out of her depth at Margate. She gained the shore greatly exhausted, and the same night had an epileptic fit, and subsequently others at intervals of a month or more, but these were without effect upon her eyes. Shortly before I saw her she had been rowing up the Thames, and fell into the water at Windsor Lock. She was menstruating at the time, and the sudden immersion stopped the process, and she became amenorrhœic. Within a few weeks keratitis, partly interstitial and partly superficial, attacked both corneæ. The inflammation was not accompanied by pain. Her vision was reduced to $\frac{6}{18}$ with the right eye and $\frac{6}{24}$ with the left. The discs could not be clearly seen. The possible origin of the disease from the reflex action of the teeth, of worms, and of constipation were one by one excluded. About a week after she was first seen pain began to be felt, which gradually became very severe, and the inflammation extended from the cornea to the iris and choroid, so that she was suffering from keratitis and from irido-choroiditis. Vision was reduced to perception of light. Dr. Gill had ordered citrate and iodide of potash, without improvement. Leeches and hydrarg. c. creta with quinine were prescribed; and cold applications proving most agreeable, cold compresses were kept constantly applied. In the course of a few days the mercury was exchanged for bromide of potassium. Improvement gradually took place. The catamenia became regular, and early in December the corneæ began to clear, and by July in the following year she could read No. 1 Jäger with each eye. I saw her one year later, and she could then read 1 with the right eye and $\frac{6}{9}$ with the left. A small spot of retino-choroiditis was visible near the fovea centralis of the left eye.

Retinitis may occur as the result of sudden suppression of the menses. M. Thaon records a well-marked case in which the connexion between the inflammation of the retina and the menstrual disturbance was well marked in a girl of twenty, of previously good health and regular, who was suddenly rendered amenorrhœic in consequence of mental excitement and family troubles. On the third day after the emotion violent headache was experienced. She had rigors, and on the seventh day the vision of the left eye was seriously impaired. The symptoms of optic neuritis were slightly marked, but at the distance of three diameters from the disc were numerous white patches along and superjacent to the vessels, with some large muscæ in the vitreous. Vision was abolished in the upper third of the field. Treatment directed to the restoration of the menses was followed in this case by great improvement, if not perfect recovery. Other cases will be found in the Journals and Reports, in which retinitis occurred sometimes with and sometimes without hæmorrhage.

Paresis of both the internal and external muscles of the eye has been noted. Hasner has reported one case of a girl aged seventeen, who, each month when the catamenia were present, was attacked with complete paralysis of the whole of the left third nerve, which lasted for three days, and was accompanied by headache and vomiting. The affection had persisted for four years, with great regularity in its recur-

rence. I suppose that we have all met with slight affections of the third nerve, in the form of accommodative asthenopia, dilatation of one pupil, and diplopia clearly attributable to the enfeeblement and general exhaustion of the system, which accompanies the menstrual discharge, and which of course brings any hypermetropic defect into prominent notice.

I have a strong impression that menstrual disorders constitute a factor in the development of the obscure affection termed conical cornea, or perhaps there may be some cause common both to the derangement of the menstrual function and to the thinning and yielding of the cornea. I have seen three or four cases, in all of whom the catamenia were scanty, the complexion pale, the expression of the face dull, and the general aspect poor and ailing. I have, however, been unable to recognise any special organ as diseased. The cases I have seen have been of the ages between twenty-eight and thirty-four or thirty-five.

One of the functional disturbances of vision that may be met with associated with amenorrhœa or with dysmenorrhœa is amaurosis, of which a typical case was reported by M. Dor to the Congress of Ophthalmology, 1884. The blindness lasted for twelve days in the right eye, and for six weeks in the left eye. There was hemianæsthesia affecting the left half of the body. With the return of the suppressed menses the symptoms cleared away, leaving the patient with perfect vision.

Some years ago I saw a patient sent to me by Dr. C. P. Tomkins of Beddington, who had long suffered from severe dysmenorrhœa. She had been a governess, and had always been delicate, hysterical, and subject to most severe attacks of neuralgia at her periods. I need not give her symptoms in detail, but she had had ovaritis, had lost her voice, had had herpes and her pulse had been 50. She complained of great impairment of vision due to a close black network, which was constantly before her eyes, and a central scotoma of the form of a hand. I raised her lids with difficulty, for she kept her head down, and light was distressing to her, and after some trouble obtained a sufficiently good ophthalmoscopic examination to assure myself that the media were clear, that the discs were whiter than natural and slightly cupped. The symptoms in this case were, I imagine, essentially reflex, and connected with the dysmenorrhœa.

Partial atrophy of the papilla may now and then occur. Galezowski[13] reports a case which, however, I should have been disposed to attribute to hæmorrhage, for in the year preceding she had had a miscarriage attended with much loss of blood. The symptoms were: Derangement of the catamenia, with headache, vertigo, and sudden failure of the vision of the left eye. Return of the menses, accompanied with much hæmorrhage, was followed by a similar attack in the right eye, and a condition of hysteria was established. No improvement took place after treatment, and the optic disc presented a condition of atrophy chiefly affecting the external segment.

The precise mode in which disturbance of the menstrual function operates in inducing ophthalmic disease is obscure. It may be by retaining in the blood, in cases of sudden suppression of the menses and in cases of amenorrhœa more slowly induced, materials that are of a poisonous nature, the action of which is indicated by the loss of blood-making power, and consequent imperfect performance of other functions, with spasms and pain in different regions of the body, in which the eye participates; or it may be by acting on the vessels of the eye alone through the nervous system in a reflex manner, and thus interfering with its due nutrition, as we know may occur in cases of dental disease and the intestinal irritation of worms.

It need hardly be said that the treatment of such cases falls into the hands of the obstetric physician in most instances, and our part is limited to the recognition of the nature of the ophthalmic trouble and to giving a forecast of the probability of improvement or complete restoration of sight. In cases of the deep-seated affections of the choroid and retina much caution should be exercised: first, because it is not possible, owing to the cloudiness of the media, to recognise the exact extent of the mischief; and, secondly, because the history of such cases shows that even when no very serious lesion is visible under the ophthalmoscope vision may long remain impaired.

(To be concluded.)

Address

ON THE

FUNCTION OF MEDICAL SOCIETIES,

AND ON THE

ABIDING IMPORTANCE OF PATHOLOGY TO CLINICAL WORKERS.

Delivered at the opening of the Session of the Glasgow Pathological and Clinical Society, Oct. 10th, 1887,

BY JAMES FINLAYSON, M.D.,

PRESIDENT OF THE GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY; PHYSICIAN TO THE GLASGOW WESTERN INFIRMARY, AND TO THE GLASGOW HOSPITAL FOR SICK CHILDREN.

GENTLEMEN,—My first duty is to thank the members of this Society for the honour conferred on me in electing me as their president for a second year of office. I believe I am not wrong in seeking the explanation of your selection in the fact that for the first ten years of this Society's existence I acted as its secretary, and may, indeed, claim to have been one of its founders. It is natural, therefore, in my present position, to inquire how far the Society has fulfilled the objects of its foundation. These objects are indicated in its name, as being for the study of medicine in its pathological and clinical aspects. But why, it may be asked, should a *Society* be formed for this purpose? Are there not books and printed lectures, and weekly and monthly journals, all ready to supply such wants? It seems to me, I confess, in the matter of Medical Societies as in the courses of instruction at our schools — the former for the education of practitioners, and the latter of students,—that the time has fully come when the great fact of the printing press, and of a cheap and valuable medical literature, should be openly and practically acknowledged. It seems an extraordinary anachronism that a medical teacher should often read to a class of students a series of detailed statements or facts, practically compiled, or capable of being compiled, from standard treatises, and that these young men should try to take down in their note-books a complicated series of facts and names, often quite new to them, when the only thing one can feel sure about in such a method is that notes so taken by them must, from their ignorance of the subjects and from the imperfections of hearing and of attention, be more or less inaccurate and imperfect. We all know from our own experience, or from observation of students, how such note-books are apt to teem with errors in names, in spellings, in quantities, and other points of vital importance, all of which could be supplied with almost absolute accuracy by means of carefully prepared text-books. The system of oral teaching had a very different place when text-books were few or bad, and apt to be antiquated; but in these days, when some of our best men write works adapted for students, when they are carefully brought up to date in successive editions, and when the cost of them is comparatively small, it seems to me that the whole system of our instruction should be remodelled with due recognition of this fact. The sphere of oral teaching, if abolished in some directions where it can be superseded by a better, could then be extended to subjects and to methods where books, however good, must wholly fail.

Now it seems to me that similar remarks apply to Medical Societies. We have all listened at them, I am sure, to admirable communications, full of interest, full of details and of facts of great importance, with a feeling that such papers were to be read, and not merely listened to. How often do we notice in a discussion which follows such a paper that the speakers feel that it would be an impertinence to criticise it seriously till they had read it. Even in less elaborate communications, how often do we see a member rising to inquire about some point in a case which had been duly stated by the speaker, but had escaped the notice of the member, even although he might be listening with great interest and attention. We all know how that in reading a medical case we have often, when we come to some point at the end, to turn back to

Digitized by Google

re-read some details at the beginning. For all such communications the printed form, with its accuracy, its facility for reference to special points, its condensation still compatible with clearness and fulness, appears pre-eminently the best. It seems to me very doubtful if the day has not passed for Medical Societies to meet formally and hear such papers as a preliminary to their publication. No doubt such papers are sometimes followed by important discussions, a form of society work to which I will refer presently.

But just as in the student's education there are methods which the books cannot take up, so in the education of the profession at Societies there are enormous advantages which no development of the periodical medical press can possibly supply. It is when we come to the demonstrative methods that we see the benefit. How imperfect, for example, are the descriptions of some rare skin disease, some intricate nervous affection, or some unfamiliar pathological appearance, even when aided by expensive engravings or lithographs. Or rather, as is sometimes said, how perfect these descriptions seem, how accurate and how full, when once we have seen for ourselves what the writers describe so well to those who know, and so unintelligibly to those who do not. Our Pathological and Clinical Society in Glasgow was founded in this view. Whatever subject might come up, we wished to have something to be shown; even comparatively trivial communications had thus an educational value; and when the rarities from the wards or the post-mortem room are brought forward, the members are supplied with illustrations which may serve to illumine their future reading on the subject. Our limited numbers, and the less formal or conversational style always permitted in our Society, enable those present to see or handle for themselves what is shown, and to grasp the points which the speaker wishes to bring forward. In this way some of our smallest and least ambitious meetings have been among the most instructive to those present. Another point aimed at in our methods at this Society was the cultivation of accuracy. When the specimen referred to is on the table for examination by experts who may be present, we feel an additional incentive to care and accuracy in our remarks and in the preparation of the case; and the educational value of bringing forward cases or specimens thus to be criticised on the spot makes this Society a valuable training ground for the younger members of the profession, for whose benefit it was specially founded. In this view, moreover, a specimen or case shown at a Society receives a certain stamp of authenticity as compared with one merely reported without being shown.

A distinctive value of Society meetings, as compared with printed matter, has always been regarded as consisting in the discussions following a communication, or in the holding of more formal and set debates. In our own Society the criticism and discussion of specimens and cases have often proved useful, and our rules give permission for the occasional carrying out of more formal debates. On four occasions during the fourteen years of its existence the Council arranged for such discussions—the first on the pathology of phthisis, the second on the treatment of internal aneurysm, the third on albuminuria, and the last on cancer. I believe the general impression amongst the profession here as to these discussions was that they were, in a sense, successful, and that they had an important value in stimulating interest in the great subjects referred to; and in all of them we had the special advantage of seeing and hearing distinguished members of the profession from a distance, who kindly came to take part in the meetings, and by their presence and the value of their communication gave vitality and interest to the proceedings. But discussions of a formal or ambitious character are apt to be disappointing; they tend to lose the character of true discussion, and to consist rather of a series of independent dissertations by the speakers, with but little reference to what had gone before. In our discussions an attempt was made to lessen this danger by the circulation of proofs of the speeches made on one evening before the resumption of the debate on the next. But the charm of a discussion is often lost when each speaker has to deliver himself after careful preparation and in view of being reported in the journals. How often do we enjoy a talk with a medical friend, when he discusses a subject with us in private, giving his speculations, his half-facts and their [illegible] could be answered [illegible] ating the matter [illegible] same person has to get up to speak in view of reporters, his imagination has to be restrained, his facts have to be reduced to a form he can absolutely stand by, and what was sparkling and suggestive is apt to become commonplace and unsatisfactory. Few men with any reputation care to commit themselves under such circumstances to express an opinion on the spur of the moment, except in the most general terms, on the views of a previous speaker, if they are in the least novel: and even if there may have been time to consider them in a printed form before resuming the debate, one who has undertaken to speak on an important subject is apt to have already decided in his own mind what to take up in his share of the discussion, and is rather chary of deviating from the lines which he had sketched out for himself. I believe a distinguished member of our profession once formulated the proposition that "accurate knowledge spoils conversation." Many interesting remarks might be made, it was said, in a miscellaneous company, when discussing almost any casual subject, say the height of a steeple or the age of a building; and stores of interesting matter and a pleasant interchange of ideas brought up from varied lands and varied experiences; but all this (so it was said) has the life taken out of it if some person unfortunately is present who can give the relative height of the steeples named in feet and the exact age of the buildings in years. So it has seemed to me that preparation and a sense of responsibility spoil medical discussions. We only care to hear the opinions of those having some claim to be heard; but it is just those men who are unwilling to discuss new ideas without time for consideration, and so they limit themselves to ground on which they feel confidence; hence it is that so very often their remarks are but partial expositions of views already published by them in some other form, without much, or perhaps any, of that active conflict of mind which we look for in a discussion.

Reviewing the work of our Society as a place where we all, without exception, could acquire much valuable knowledge, where many of us have been trained to habits of accuracy and precision in preparing and showing our cases, where a stimulus and encouragement to honest work, especially amongst the younger members of the profession, could always be looked for, I believe I may safely say that the influence of this Society has been very potent for good; and its discussions, exciting as they did much general interest in medical circles, had, in addition to the mere value of the communications, a useful influence in adding to the medical life of our city.

Coming now to a wider subject, I would like to ask, What is the really important relationship between the two great subjects, the cultivation of which is aimed at by our Society, as indicated by its title of "Pathological and Clinical"? What is the relationship of pathology to clinical medicine and surgery? It might seem at first sight that this was very plain, that pathology, or the science of disease, must constitute the very foundation of what we observe and what we treat when called to the bedside of the sick. I remember one of my students, some years ago, saying to me how much he was interested in pathology as a fascinating subject in itself, and as forming the very basis of all medical and surgical practice. I said that it was natural for him as a student who had only learned one pathology, and that the newest, to think in this way; but that he must remember that the pathology he was learning was utterly different from that of even twenty or thirty years ago, and that the pathology of the next twenty or thirty years would no doubt be very different from what he had learned; in the meantime the patients and the diseases and accidents were very similar, and that clinical medicine and surgery must be founded on something less shifting in its character. I put the changes in pathology in large cycles of twenty or thirty years, but one would scarcely be wrong in saying that this science gets almost revolutionised every few years, so as to be scarcely recognised as the same subject. Taking changes and innovations promulgated, or at least generalised, within the experience of many of us here present, what would our pathology be like if we had to cut out of it all ideas of embolism, septic as well as otherwise; all ideas of the migration of leucocytes, and all ideas of micro-organisms and germs? But there was a pathology long before these notions were current, a pathology cultivated by such master spirits in the profession as Morgagni and John Hunter. It would ill become one who has been, by your kindness, elected president of a Pathological Society to speak disparagingly of pathological science, but I have often wondered in my

Digitized by Google

own mind wherein lay what I felt to be the enormous value of pathology to the art of the physician or surgeon in his clinical work. One cannot help feeling that the value of Hunter's surgical work, and even more notably of his mighty influence, turned on his extraordinary energy and brilliancy as a pathologist; but equally one cannot help feeling that it could scarcely depend on the value of his mere pathological facts, or on the soundness of his views, for these of course have been displaced or superseded to a great extent by the progress of the very science which he did so much to found. It would seem as if some more stable influence than the knowledge of shifting pathological data must be at the bottom of the important relationship referred to—the relationship of pathology to clinical work.

Coming down from the great masters of our art and science to our own level, I would ask what is the secret of the enormous advantage which we have when we have attained to the position of physicians and surgeons to the hospitals and infirmaries of our city? No doubt in the wards we see many unusual cases not otherwise available, but I am sure that all must admit that specially great advantage arises from the opportunities presented to us in the pathological theatre for observing the state of parts after death; or, in the case of surgery, in the limb or tumour removed by operation. It may be contended that we have in this merely an additional field for the acquisition of facts bearing on our art, and that it is only natural that those with wider and more varied fields of study should thereby derive greater profit. It seems to me, however, that there is more than this.

Pathology is not a mere collection of facts; if it is to be a living influence it must be a more or less compact body of doctrine, relating these facts to each other and to the processes going on in the living, as well as to the results found in the dead. I suppose we all require to have some such doctrines in our minds, vague or definite, held firmly or loosely, formulated hypothetically or dogmatically, as the case may be. I have sometimes been struck by the air of certainty and authority with which some members of our profession speak regarding the pathological processes going on in their patients; they seem to see the exact state of the cells of their livers, and the varying condition of these and of the epithelium of all the mucous membranes, with every change in the disease, or with every variation in their remedies. Of course with such men their diagnosis is as certain as their pathology and their therapeutics. But this type of mind is usually outside of our hospital staffs; for, as I daresay you all know, it is not very infrequent for the hospital physician to find his pet theories of an illness rudely upset when the case comes to the post-mortem table in the presence of his students; and even our friends the surgeons sometimes get a rude awakening at the operating table in a crowded theatre. Working under conditions of this kind, where errors in our diagnosis, pathology, and treatment are constantly liable to be brought to light before competent and incompetent judges (the competent being usually much the more charitable of the two), one is almost forced to learn to separate what he is sure of from what is merely highly probable, or what is quite speculatively problematical. Such a one may, indeed, at times speak with a certainty and a dogmatism on some points in diagnosis or pathology which might astonish even the other type of mind to which I have referred; but very often this certainty is limited to special points only, and these not always the most vital; he may be certain of an enlargement of the liver or of a consolidation of a lung, but may be doubtful as to the nature of the enlargement or the cause of the consolidation. Trained to work under the possibility of constant checks, one is almost necessarily led to be more accurate and careful in diagnosis, trying to omit nothing which is likely to throw light on the disease, keeping pathological speculations well in hand, always discriminating between those parts of the diagnosis or pathology which are securely established, and those on which more or less doubt may still linger, acquiring in one way certainty and decision, in another openness and flexibility of mind. Dealing with hidden processes of disease, the physician is sometimes tempted to arrogate an infallibility of judgment which public opinion at one time tended rather to force upon him, or to adhere to doctrinal traditions which he may have inherited, and may, as a teacher, be himself transmitting; but all such tendencies receive constant checks from the facts of pathological anatomy, for our nationality and the spirit of our times are both distinctly adverse to the well-known retort of one whose theories were convicted of being at variance with the facts, when he said, "So much the worse for the facts."

We seem, then, to see in this relationship of pathology to clinical work something of the same kind of advantage which I referred to in connexion with the presentation of specimens or cases to a medical society, where the tendency is to care in the preparation of the case, accuracy in statement, and liability to correction or criticism from the scrutiny of other observers whose habits of mind lead them to look at things from a different point of view. It may, however, be contended that pathology might be an admirable check and guide to the clinical worker if its data were accepted as ultimate and absolute facts, but that any such test becomes illusory, and perhaps even fallacious, if pathology be admitted to be in such a constant state of flux that books five or ten years old cease to be adequate guides even for our students, while the great masterpieces of the last generation of pathological workers are only consulted as interesting historical records, or for the artistic beauty of their illustrations. Now, of course, in this department of science, as in all others, the great sweeping changes which occur from time to time always leave an ever-growing residue of facts more and more firmly established amidst the shaking of others; and in a multitude of cases it is the interpretation, rather than the fact, which is called in question and changed. No doubt this is sometimes so radical in its character as almost to amount to the substitution of a new fact for the old. When Rayer figured with such accuracy the lesion in the kidney which his experience showed to occur in rheumatic subjects and called it "néphrite rhumatismale," we have his fact remaining, in a sense, although in another sense we also change it, ceasing to regard it as "rheumatic nephritis," when we know it to be due to a mechanical plug or embolism, even although rheumatism may have been the origin of the whole mischief, as it usually is. But the facts of pathological anatomy and an ever-growing body of pathological doctrine resting on a sure basis may well be looked up to in connexion with the mysterious processes of disease as affording, as a rule, a tolerably sure court of appeal to the clinical student. Even, however, if pathology were much less certain than it is, and even at the times when it was much more imperfect and much less worthy of confidence, we can understand that in the check afforded by the facts of morbid anatomy and the observation of pathological processes, so far as this was possible, the physician or surgeon might find the greatest guidance in his work. The tendency of many, perhaps most, minds in our profession is to theorise and speculate, and to spin fine webs out of our own heads. Our great pathologist revealed his method in a couple of words in writing to Edward Jenner, when he said, "Why think?"[1] To observe, to inquire, to compare, and to experiment where this was possible, these were Hunter's methods. But in thus bringing us ever close to nature and to the observation of her methods, in subordinating theoretical doctrine to the observation of nature and facts, Hunter was teaching himself and all his followers a lesson not merely useful for the pathologist, but of paramount importance for the surgeon and the physician. To be guided in the observation and treatment of disease by the facts which lie open before our eyes is the great qualification of the clinician. How difficult it is to observe disease apart from theoretical or doctrinal considerations, no one would, *a priori*, imagine. But it is well known that we all pass by, as if blind, certain obvious features of disease, which are so glaring that when a new disease or a new symptom of disease is described by some true clinician, immediately throughout Europe and America confirmatory cases, hitherto ignored, are at once recognised. If this be so in diagnosis, we need not wonder if in treatment we are equally blind, and that methods are pursued for years or for generations which are ultimately discovered to be either useless or injurious, or of but trivial value.

It is, I believe, in tending to keep us to true facts and to the observation of nature that pathology supplies a great and abiding influence for good on clinical work. No doubt pathology itself is uncertain in many ways, and, as I have ventured to say, in a state of flux; but the very fact of this constant change in an allied science makes the physician or surgeon keep his mind ever open to new facts and to new ideas, which may, whether true or false, serve the useful

[1] Hunter's Works, Palmer's Edition, vol. i., p. 56.

Digitized by Google

purpose at least of keeping him on the alert, and of saving him from degenerating into a degrading routine or a dogmatic obstinacy. It is vain to complain of the imperfections of pathology; it is better to try to improve it. Clinical medicine has been under enormous obligations to the pathologist, and it is right that it should exert itself to help forward pathological inquiry. In the foundation of our own Society it was felt that neither had an independent existence apart from the other, and that, with us at least, they should not be dissevered. The genius of the greatest living pathologist recognised the wide reach and close interrelationship of different methods in the study of medicine. Long ago Virchow[2] sketched out his *Handbuch* of medicine to supply from the best writers he could find a systematic statement of our knowledge in its various branches. But he likewise organised in his *Jahresbericht* a repertory of new and contemporaneous work in all countries to supply the means of checking and correcting our ideas up to date. In his *Archiv*, which may be taken to represent living and original work, he clearly expresses in its title that it was to be no mere receptacle for dead morbid anatomy, but that it was to extend to the physiological as well as the anatomical aspect of pathology, and *likewise to clinical medicine*, a relationship which this *Archiv* has done so much to uphold.

The value of the contributions which clinical work may make to pathology seems to me to be well illustrated by one of the newest departments of pathological research. The far-reaching influence of minute organisms and germs in our science at the present time calls for the accurate recognition of one set of germs from another, which, while so far similar, may yet be utterly different—the one full of mischief, the other essentially harmless. The difficulty we have to contend with arises from mere morphological distinctions often failing us: an organism in its life history may go through many forms, and may vary with the media of its cultivation, so that what seem to be very different may be really the same; on the other hand, organisms very similar, practically identical in form, may be utterly different in reality. As you all know, the pathological bacteriologist seeks to prove his germs by cultivation, tracing the history of the organism in its various phases and in various media. It is just this kind of service which clinical workers can render to pathology,—not indeed in cultivating disease, but during their efforts at suppressing it, by watching its life history, the variations which the diseased condition undergoes in various parts of the body or at different periods of the patient's life, or in the transmutations brought about in different generations. This life study in the human subject must ever be the accompaniment and corrective of a true pathology, however carefully it may otherwise be studied on the dead subject, or even by experimental researches on the lower animals. In the recent discussion held by this Society on the great subject of Cancer (1886), Mr. Jonathan Hutchinson said "that it seems just possible that the turn of the clinicists is again coming round," and various matters were raised even at that discussion which only clinical workers can solve. The remarkable suggestions and instances of apparent transference of this disease from husbands and wives, raised at that discussion, call for the close attention of clinical inquirers. The family history of patients, if scrutinised in the future, may throw much light on the vexed question of the relationship of sarcomatous and carcinomatous tumours, if, as I am inclined to believe from fragmentary information brought to my notice, it may yet be shown that the same families breed both sets of growths. As yet, however, inquiries on this matter are beset with this difficulty, among many others, that what, even a few years ago, and by pathologists who recognised the distinction, were put up in our museums as cancer would now by the same men be labelled sarcoma; as time extends for us, however, the available mass of reliable materials, we may be able to show that, as in the case of the germs already referred to, what is morphologically very distinct may be really very similar when submitted to the test of cultivation. At a previous discussion in this Society on Phthisis (1881), some of us, as physicians familiar with the life history of this disease, refused to separate at the dictation of pathologists what we felt to be allied, although on the ground of histology we might feel that we must appear to be hopelessly beaten;

[illegible]

[2] Handbuch, 1854; Jahresbericht, 1851; Archiv für Pathologische Anatomie und Physiologie, und für Klinische Medicin, 1847.

but since then the developments of pathology itself have tended to include in one common group not only various forms of pulmonary disease at one time separated from each other, but also other manifestations of so-called "strumous" and "scrofulous" disease, which had always been felt by physicians to be closely allied in their family history to phthisis and tuberculosis. In thus recalling an incident, full of significance as I believe, I do not of course wish to stir up antagonism or recrimination between pathological and clinical workers: the best men in both departments feel that these subjects must go hand in hand, and that they cannot be divorced from each other without risk of grave disaster. Such was the view of the founders of this Society, and I hope that its work in the future and its influence on its members may be such as to strengthen this alliance, so that our Society may truly deserve its name of "Pathological and Clinical."

SEVEN CONSECUTIVE CASES OF LAPAROTOMY.

By W. BALLS-HEADLEY, M.A., M.D. Cantab., M.R.C.P.E.,
HON. PHYSICIAN TO THE WOMEN'S HOSPITAL, MELBOURNE, VICTORIA.

(*Concluded from page 1010.*)

Case 5. *Fibro-cystic Disease of the Uterus: Oöphorectomy; Recovery.*—Miss De L——, aged forty-seven, has been attended by me for the last nine years. I first saw her in consultation with Mr. Rudall, who desired me to take the case. Up to June, 1880, she had been subject to frequent and violent uterine hæmorrhage, with fibroid of the uterus, reaching half way between the pubes and the umbilicus. She had taken large quantities of ergot for considerable periods, and at intervals ergotine had been systematically injected after Professor Simpson's method, at first apparently with some benefit, then without. The cervix had been divided, and the posterior thickened uterine wall incised. Again the cervix had been dilated and the uterine wall incised. The hæmorrhage then ceased, though the catamenia was rather profuse, and she gained strength and colour, but there was an enormous flow of clear, straw-coloured fluid, which was almost pure albumen, or as if blood without the colour.

June 28th, 1880: Solution of persulphate of iron was applied to the os, and repeated frequently. Ordered twenty minims of liq. ergotæ three times a day.—August 11th: Still loses large quantities of the fluid. Removed a large rotting white clot from the upper vagina. The interior of the uterus fluctuated, and the sound was introduced into it, when a thin, brickdust fluid escaped, and a fresh blood clot followed. Injected iodine into the uterine cavity.—13th: Applied the iodine on cotton to the uterine cavity, and left it there.—14th: The cotton had not remained in the uterus.—16th: Lost a great deal of the clear fluid. Plugged vagina with iodised cotton.—17th: Lost very little.—September 4th: Catamenia should have occurred on August 23rd, but has not appeared; much less watery discharge; looking well.—October 9th: Catamenia not appeared looking well; watery discharge comes with a rush with white clots, then a little for two or three days. When the discharge is less she feels tighter and larger; the abdominal tumour is large and hard. The os admits to the first joint of the finger, when the edge of something, perhaps a white clot, is felt. The uterine surface felt around the clot is soft behind, it is felt as if fluctuating.—December 13th: The catamenia had not appeared for three months, but a half till November 7th. The watery discharge had also stopped gradually and entirely for three days, when she walked much about town and went to the Exhibition, where she was much squeezed in a great crowd, especially on the abdomen. The catamenia came on the next day and lasted a week; then there was an interval of three weeks, duration four days, with clear discharge and white clots between. The abdominal tumour extends above the umbilicus. The os is well open; there is a soft substance [illegible] which the sound easily passes. Applied solution of persulphate of iron.—15th: Very quickly, and

incompletely, I introduced a little iodised cotton inside the uterus.—18th: Better; applied iodised cotton internally and at the os.

April 5th, 1881: For the last three weeks has had pain at the epigastrium, and could not stoop. Ten days ago had much watery discharge, and I introduced iodised cotton within the cavity, and the fluid diminished. Now has pain again, and loose black stools. Within the os is felt a large tongue-like mass, differently adherent; easily breaks down. Pulse good; colour fair. Last catamenial interval four weeks, duration five days.—June 23rd: Cramps and œdema in legs; watery discharge moderate.—30th: Last catamenial interval three weeks, duration three days, with great pain and moderate quantity; ceased three weeks ago. Has a firm, easily movable tumour reaching above the umbilicus. The os uteri is high, and protruding through it is a tongue-like mass. The legs are œdematous; urine albuminous; heart, lungs, and liver normal. The watery discharge is not so large, yet constant. In view of the albuminous urine a large operation was deemed to be undesirable, if avoidable, and she was ordered iron and ergot. If the polypus should become more vaginal an operation could be performed; if not, the necessity could be considered a little later.—Aug. 15th: Polypus projects a little more from the os. Pulse 112; looks thin and pale; cough. Iron and ergot to be repeated.—Sept. 7th: Polypus projects much; bad catamenia, with maddening pain, and not quite stopped yet.—13th: Yesterday had a squirt of bright blood, then a flooding of clear fluid; urine pale, specific gravity 1003, slightly albuminous.—14th: Dr. Burke administered methylene, and I introduced the hand into the uterus and broke up quantities apparently of cysts with thin coverings, no solid substance being removable, but the débris being shreds. The os was also thoroughly cleansed of the projecting tumour of the same character. In the operation, the vagina, being very small and undilatable, was ruptured from below the uterine junction posteriorly, through the perineum, showing the external surface of the rectal sphincter. The wound was carefully sutured from above downwards. The temperature reached 101°, but she recovered well, the discharge ceased, and three weeks afterwards had her catamenia as a slight red discharge.—Nov. 11th: Has had a slight red, thin discharge daily, requiring less than a napkin. Now her complexion is red. The fundus of the uterus can be felt just above the pubes. The vagina is perfectly healed, as well as the os. The uterus measures two inches and a half. Nothing but thick uterine walls noticeable.

March 6th, 1882.—Wonderfully well; walks, eats, and is quite well, fat and rosy. Catamenial duration three days; occasional slight "whites." Abdominal walls very fat. The uterine tumour extends half way to the umbilicus.—May 22nd: Looks well and fat and very jolly. Has rheumatic pains in knees and rolls her stockings down. The uterine tumour extends to the umbilicus and much in the right iliac region; the sound enters five inches and a half; the uterus is drawn up from the pelvis, the os is nicely open, and nothing abnormal is perceptible by the vagina but the tumour on double palpation. Catamenia normal, and scarcely any discharge. To have half a drachm of the solution of ergot night and morning.

July 21st, 1883:—Catamenial interval from two to four weeks; duration from ten to fourteen days, not much after four or five days. Looks well. The tumour is below the umbilicus and small; the os is soft. To take a draught composed of quinine and sulphate of magnesia with dilute sulphuric acid.

Feb. 8th, 1884.—The catamenia was regular at intervals of three or four weeks; then ceased for three months, with a constant, slight, coloured discharge, and she got enormously large in the abdomen, when the catamenia recurred two weeks ago for a week and in large quantity. Now says she is large and thinks the tumour is growing. There is a round central tumour to half an inch above the umbilicus, with sense of fluctuation. The internal os is open and admits the finger, but the external vagina limits its introduction. The sound passes readily five inches. I think the uterus is full of gelatinous tissue and fluid as at the operation. Ordered a three-grain ergotine pill night and morning.

Jan. 14th, 1885.—Complains of palpitation, shortness of breath, menorrhagia, large quantity of "whites," and nervousness. The catamenial interval is two weeks, duration seven days; very great pain for previous two days; quantity very large, requiring eighteen diapers a day. A large tumour occupies the abdomen to three inches above the umbilicus. The right loin is resonant, the left less so. The os uteri is large, the anterior lip being greatly broadened and apparently fluctuating. To have half a drachm of tincture of sesquichloride of iron three times a day.—Feb. 3rd: Feels strange, but has pains in the abdomen from the large swelling. Last catamenia ceased Jan. 3rd. Says that sixteen months ago it ceased for three months, and has recurred in floodings since taking the three-grain pill of ergotine.—March 11th: Catamenia recurred on Feb. 6th, duration one week, with violent pain; and again on March 4th, which is just over; lost a large quantity; took four bottles of tincture of sesquichloride of iron. "Whites" stopped; she had great pain and swelling, but the medicine made her stronger. To repeat the sesquichloride of iron (half a drachm), and to have cold vinegar-and-water injections.—April 7th: Had a heavy flooding for four days after an interval of one week.—Nov. 14th: Catamenia regular, with an interval of from two to four weeks, and a duration of from ten to fourteen days; the last ceased Sept. 10th, and then she had great pain till two weeks ago, when the catamenia was induced by hot poultices for two days, and she had a slight discharge. Says she now feels very large, with pressure upwards, shortness of breath, and pain, but feels stronger now that she has no floodings. The tumour reaches to the ensiform cartilage, and extends across the abdomen, distending it greatly; it is tense and hard. By the vagina the sense of fluctuation is very strong. On Nov. 27th I introduced my dilating trocar into the tumour in the anterior lip by the vagina and drew off four quarts of clear yellow serum, which coagulated rapidly, and introduced a drainage tube. It continued to drain for two or three days, when the abdominal tumour was hard and reached only to the umbilicus. After five days she had hæmorrhage for twenty-four hours and got very low. In January the catamenia was normal and had not recurred on April 3rd, except for a slight show every ten or twelve days, which had then lasted fourteen days. Had continuous nausea and pain across the epigastrium, and food created fulness but no vomiting.—On April 3rd the tumour receded to the ensiform cartilage and was as before, and I thought I could feel the left ovary to the left of the umbilicus. Had enlarged greatly in the last month. The anterior cyst was again emptied per vaginam, and on Aug. 8th five pints and a half was similarly evacuated, and on the 25th a smaller quantity. On the 26th, in accordance with the opinion of the hon. staff in consultation, Dr. Burke administered methylene, and, assisted by Drs. Fetherston, Rowan, Hooper, and Lynch, and in the presence of other medical men, I, by an incision an inch and a half long, removed both ovaries, which were cystic, the left of normal size, the right as large as a hen's egg. The operation from beginning to end occupied twenty-five minutes. The temperature did not exceed 100°, nor the pulse 100, and she made a perfect recovery, though she had a small parietal abscess. The tumour at once atrophied. On Oct. 29th she was quite well, and had had neither catamenia nor discharge. The tumour was felt indistinctly, except on double palpation, when it felt moderately firm, and so by the vaginam, but not cystic. The abdomen was resonant above, half way between the pelves and umbilicus.

I have ventured to be wearisome in the details of this case to show the following points:—1. The gradual development of a fibroid uterus into fibro-cystic disease of the uterus during a period of nine years. 2. The variations between amenorrhœa and menorrhagia, with invarisble increase in size during the former. 3. The complete practical inefficacy of ergot, ergotine, and ergotine injections, continued for years; of iron, intra-uterine applications, divisions of the cervix, of the walls of the tumour, of cleaning out the cavity of the uterus, and of draining the cyst; and the final and complete cessation of the refilling of the cyst, and the atrophy of the fibroid uterus, and restoration to complete health by the removal of the diseased ovaries.

CASE 6. *Fibroid of the Uterus; Oöphorectomy; Suppurative Peritonitis; Death.*—Mrs. J——, aged forty-nine, was a patient of Dr. Dowling, with whom I saw her in consultation. Had been married thirty-two years, and thinks she had a miscarriage twenty years ago. Seventeen months ago she began to lose blood, which has been continuous since, and frequently in very large quantities, which only stopped a little when treated by Dr. Dowling. When I first saw her she was a large anæmic woman with a thin pulse; an abdominal tumour, hard and solid, reached from the pelvis to the level of the umbilicus, into which the sound

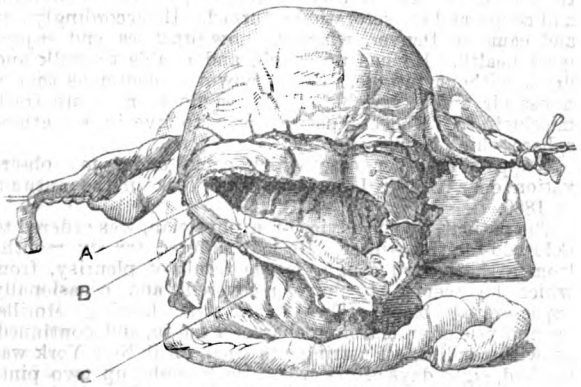
Digitized by Google

entered four inches and a half. It was decided to admit her to the Women's Hospital, where, in consultation of the staff, it was determined to remove the ovaries. The operation was performed on Oct. 11th, when Dr. Burke administered ether and methylene, Drs. Fetherston, Rowan, and Hooper assisting; and, in the presence of Drs. Brett, Doyle, Joske, and Meyer, I made an incision an inch and a half long below the umbilicus into the abdominal cavity. The left ovary was situated below a pear-shaped subperitoneal fibrous outgrowth, and was a little difficult to find, and, being to the surface, it was ligatured with a Tait's knot; it was small and completely cystic. The right ovary was of the size of a small hen's egg, was cystic, and a broad cystic state continued on to the broad ligament, so that the ligature had to perforate and encircle a pedicle in part cystic. The proximal cysts were lightly punctured in two places, but the point bleeding, a fine ligature was placed round it. There was no hæmorrhage or bruising of the tissues beyond what such a slight operation necessitated. The patient appeared to go on well for several days, but the abdomen became gradually distended, and she had great pain in the right hypochondrium; it was evident that general suppurative peritonitis had supervened, and it was deemed useless in the face of this condition, and as the fibroid uterus prevented pelvic drainage, to attempt further abdominal interference, and she sank on Oct. 20th, nine days after the operation. There was no further hæmorrhage by the vagina after the operation.

The post-mortem examination was performed on Oct. 21st. The abdomen was much distended, pus welling from an incision in the abdomen below the umbilicus. The edges of this wound showed little tendency to heal; they were slightly gaping and of a dirty black colour. Intestines much distended with flatus. Omentum bound down to the intestines by recent lymph, which also covered the whole of the abdominal organs, being particularly abundant on the under surface of the liver and about the uterus. The peritoneal cavity contained an abundance of pus: peritoneal vessels injected and greatly congested. Besides the recent lymphy exudation, the intestines were in part bound to each other and to the uterus by firmer bands of considerably older date, especially in the region of the uterus. Lungs: Some old adhesions posteriorly near the base of the left lung; in both pleuræ there was a limited quantity of blood-stained serum. The bases of both lungs, more especially the left, were hypostatically congested, friable, with some patches of extravasation, and furnishing on pressure some considerable quantity of blood-stained frothy fluid. The upper lobes of both lungs were emphysematous, anæmic, dry, and pale. Heart: Right side filled with dark clot, which extended into the pulmonary artery. Left heart empty, contracted; left ventricle somewhat hypertrophied, firm, fleshy. Pulmonary artery hypostatically stained. Spleen friable. Kidneys subgranular, congested; cortex broad; some unravelling of the base of the pyramids. Liver enlarged, pale, friable, fatty. Uterus: There were two or three pedunculated fibroids posteriorly near the neck, several small subperitoneal fibroids, and a large fibroid of the body.

It may well be asked why this woman died of suppurative peritonitis after an operation which in itself appeared so simple. It is true that the liver and kidneys had undergone degenerative changes, probably from the large and constant hæmorrhages; but the operation had been quick, without exposure of the abdominal contents, and the shock very slight. It is certain, in my opinion, that no contamination had occurred from sponges or instruments, for I am personally responsible for these, and know that they were clean. On the other hand, the conditions under which she was placed, and of which at the time I was not aware, are not beyond criticism; and to these I believe may be ascribed the absence of recovery. A public hospital is less under one's control than a suitable private house.

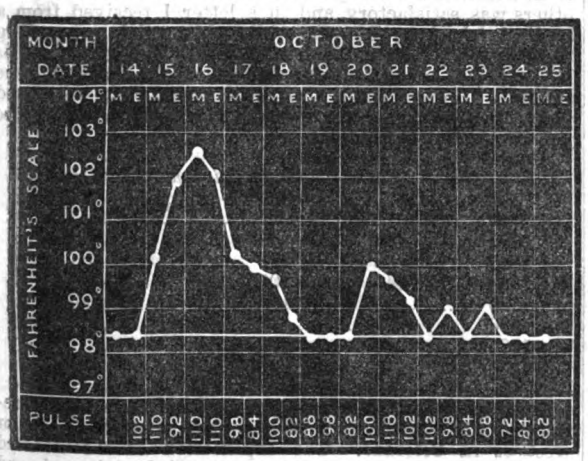
CASE 7. *Case of Porro's Operation on a Rickety Dwarf; Recovery.* — Catherine C——, aged seventeen years, was sent to me by Dr. Tuthill, and consulted me on July 7th, 1886. Her catamenia were always regular four or five months previously, the dates being uncertain. She is 4 ft. high, rickety, and malformed. The head is large, and she looks forty. The arms and legs are particularly proportionately short. The finger tips reach only to the anterior superior iliac spines, the humerus measures 6 in., the forearm 6½ in., and the hand 5 in. The thighs are 9 in. long, the tibia 9 in., and through the foot to the heel 2 in. The lumbar curve is particularly marked. At this date the abdomen was very prominent, the uterine tumour extending to halfway between the umbilicus and ensiform cartilage. The fœtal head could be apparently felt above and a little to the right of the pubes. The fœtal heart was heard 2 in. below and 1½ in. to the right of the umbilicus. The child thus lay with its face forwards. The placental souffle was most distinct just above and to the left of the pubes. The vagina had no hymen, and was patulous. The os uteri was so high as only to be just felt when meeting with the palm anteriorly, and the opening was small. The cervix projected diagonally through the perpendicular space of 1½ in. formed by the sacral prominence being superior to the pubes, instead of obliquely behind. The sacral curve was very marked, forming apparently half a circle. The following were the measurements:—Between iliac spines, 9 in.; between iliac crests, 9⅞ in.; external conjugate, 6 in.; from lower border of symphysis to top of coccyx, 2½ in.; conjugate vera, 1½ in.; Wood's inclined conjugate, 2 in. The patient was admitted to the Women's Hospital, and after consultations of the staff it was determined that Porro's operation should be performed at a later period of her pregnancy, and she returned home.



On Oct. 14th, when the child was supposed to be between eight and nine months old, assisted by Drs. Fetherston, Rowan, and Hooper, Dr. Burke administering methylene, and in the presence of Drs. Tuthill, Brett, Doyle, Forster, Meyer, J. P. Ryan, Shields, and Snowball, I made an incision four inches long from just below the umbilicus to two inches above the symphysis pubis, through the abdominal wall. A transverse cut one inch in length opened the uterus, and was rapidly extended by tearing to the limit the abdominal incision permitted. The bulging membranes were then opened, but the child's neck could not be grasped, as it had previously been recognised that it lay too high with respect to the incision, but the head was expelled by the considerable uterine contractile force and some external pressure around it through the opening, which was just large enough to let it squeeze through. The child, a girl, immediately cried lustily, and was enveloped in flannel. The hand then grasped the neck of the uterus, and Lawson Tait's uterine clamp adjusted below the level of the opening of the ovaries and Fallopian tubes. At this time the placenta was seen to be presenting at the uterine opening, and to be free from the neighbourhood of the neck, where by auscultation it had appeared to be attached. A sound was introduced into the bladder, and as it appeared not to be included in the clamp the latter was tightened up. The uterus was then cut away with scissors below the level of the transverse incision, the cavity cleansed and closed by six silver sutures above the stump and one below it, and intervening horsehairs, the stump touched with solid perchloride of iron and a strip of lint applied under the ends of the clamp wire, carbolic absorbent cotton over all, followed by Mead's plaster and a flannel bandage. There was practically no hæmorrhage except a little free bleeding when nicking the uterus, and what escaped from the uterine division after its constriction. The whole operation, from its commencement to the removal to the ward, occupied twenty-five minutes, and was very simple. The membranes were afterwards found to be closely adherent to the left uterine wall.

The progress was uninterrupted, except that by the twenty-second day the temperature had risen to 102·5°, and the pulse to 110, and jaundice was threatened, but dispelled by ten grains of calomel, which produced free action on the fourth day. On the seventh, eighth, and ninth days there was some diarrhœa, which subsided under a milk diet, and chalk mixture with solution of opium (five minims). On the tenth day the temperature fell to the normal, but was again variable from half a degree to a degree till Nov. 4th, when it rose to 102°, owing to the passage of a large hard stool and a small parietal abscess, and from Nov. 6th has been quite normal, but during all the time she seemed quite well. The stump, being broad, presently became offensive, but this was removed by iodoform and charcoal poultices. The clamp was daily tightened, and came off on the thirteenth day, when the line of separation had occurred below its level, leaving a concavity in the proximal end of the stump, through which a probe could be passed deeply into the cervical canal. No opium was given except a morphia suppository after the operation, and that for the diarrhœa. The sutures were removed on the eighth and tenth days. On Nov. 9th the temperature and pulse were normal; she ate and slept well, the abdominal wound was nearly closed,

Digitized by Google



and a little induration caused by two small suture abscesses had nearly disappeared. To-day (Dec. 12th) she is up and quite well. The baby (a girl) has been wet-nursed, and looks bright and well. I am much indebted to the able paper of my friend Dr. Godson.

I think there can be no doubt that this girl would have died had Cæsarean section only been performed, for the opening of the os was very small, would not have been dilated by labour, and the discharges could scarcely have had such a ready escape thereby as they would probably have had through the opening in the body, whence death would have ensued. Moreover, the height of and consequent difficulty in reaching the os would have prevented

Uterus removed by Porro's operation, Oct. 14th, 1886.
A, Opening for removal of child. B, Level of removal of uterus.
C, Placenta.

its manipulation, and the cavity of the uterus could in no case have been syringed. Great care was taken to avoid enclosing the bladder or ureters by applying the clamp only just below the ovaries and Fallopian tubes, which appears to have been at the junction of the lower third, the uterus being finally cut across an inch below the opening made into it for the removal of the child. The contraction of the uterus after the rupture of the membranes was very rapid and firm on to the child, and subsequently the placenta, which was not touched except to feel with the finger that it was free from the constriction of the clamp. There was no defined reason for the threatened jaundice, of which there was no doubt, but which at once yielded to the

ten grains of calomel, but without action of the bowels till two days later. The external pedicle appears to be a sad and coarse necessity, but the rapid contraction of uterine tissue so far bars an intra-peritoneal method, and the question arises whether the nutrition of so large a distal constricted mass would be usually sufficiently maintained by contiguity to avoid gangrene, which in the case of an ovarian pedicle is by the lowness of its tissue and its comparative smallness so much less imminent. I believe that this is the first case of premeditated Porro's operation performed south of the equator. (See annexed engraving and chart.)

None of the foregoing cases were performed under the influence of special antiseptics, as I have passed through the various phases of no antiseptics, complete antisepticism, the previous saturation of the atmosphere by carbolic spray, and of the most complete cleanliness, and have concluded that the last is best. I have to thank Drs. Hooper and Lynch, the resident surgeons, for their careful attention in the after treatment of such of these cases as were in the Women's Hospital.

Melbourne, Australia.

THE CLIMATIC TREATMENT OF PHTHISIS IN THE STATE OF COLORADO.

By M. CHARTERIS, M.D.,
PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, GLASGOW UNIVERSITY.

(*Concluded from page 1008.*)

OUT of three hundred notes of cases of phthisis kindly presented to me from the archives of Dr. Denison at Denver, I have selected two as bringing out important points connected with the first stage of the disease, one with the second, and a third with fibroid phthisis. We shall now proceed to speak of these.

Phthisis with hæmorrhage; arrest in first stage.—M. B——, a medical student, resided until 1876 in Chicago, since then in Colorado. There was no hereditary predisposition. In July, 1870, he had slight hæmoptysis after great exertion in a gymnasium, and the hæmoptysis recurred during the next two months. Afterwards he enjoyed good health until the autumn of 1872, when there was a severe attack of hæmorrhage. During the winter he lost considerably in weight, and in February he went to Louisiana, and returned to Chicago in the beginning of May, when he consulted a medical gentleman, who thus reported on his case: "I found the chest well formed, but the motions of the left side were restricted. Inspiration over the whole of this side was feeble, and over the right side normal. The percussion sound was elevated in pitch over the left side, and dulness was marked over the inferior portions. On the right side percussion was normal. Pulse 108. Expectoration not copious." In company with his brother he came slowly to Colorado. The high altitude seemed to suit him well, for he felt splendid, and stated that his lung "was much cleared up." After remaining quiet for six months he proceeded to a ranche near Denver, where he remained eighteen months, working, riding, and hunting. Subsequently he came to Denver and studied medicine. His improvement has been almost uninterrupted since he came to Colorado. There is no cough and no expectoration. Pulse 75; temperature normal; weight 162 lb. The last examination of him which was made showed that "he measured thirty-seven inches round the chest; below the clavicles the movements were normal, with no depression. Percussion, however, revealed a slight depression in the third interspace near the sternum, where possibly the hæmorrhage originated; over that spot, also, bronchial breathing was detected."

First stage further advanced; recovery.—G. M——, aged twenty-four, an architect by profession at Pittsburg, Pennsylvania. There is no hereditary taint, as his parents are living and well. He commenced to get weak four years ago, and his weight fell from 167 to 115 lb. This weakness was accompanied with cough and slight expectoration, and resulted in hæmoptysis. During the summer of 1881 he tried various climatic health resorts, as S. Carolina and Bethlehem, and in the fall he went to England and remained three weeks. Feeling himself no better, he came to Denver, and on examination it was found that his temperature at 11 A.M. was 99°F., pulse 88, respiration 17. There was slight flatness at the left apex and proportional expansion at the right infra-clavicular region. The right shoulder was higher than the left. Dulness was detected at the infra-clavicular region of the left lung, and also at the supra-spinous and inter-scapular spaces. Over these parts there was also bronchophony and bronchial breathing. He remained in Denver during the winter and went to a ranche in summer. In the fall he weighed 130 lb.; his temperature was 98·5° at 11 A.M., his pulse 80. Steady improvement followed, and he now enjoys good health, His present condition shows the chest to be well formed. The right

Digitized by Google

shoulder is, however, higher than the left, and the breathing is a little hard and bronchial at the infra-clavicular region; but no râles can be detected.

In the two cases narrated we have recovery from the first stage of the disease when the consolidation has not broken down; but in the second stage the state of the lung is different; for in all probability a cavity has formed where the condensation previously existed. This cavity may be chronic in type, secreting pus, but not increasing in size, or it may be enlarging by caseation and ulceration. The happiest issue of such conditions now is that the sides of the cavity gradually approximate, and form at length a tough cicatrix, which steps, however, may cause a stretching of the surrounding tissue and displacement of the neighbouring organs. Should the cavity thus heal, the cavernous sounds disappear, and are replaced by harsh breathing. In some cases also, owing to adjacent lung tissue being drawn across, a natural respiratory sound is detected.

Phthisis in the second stage.—J. H. B——, aged thirty-seven, with hereditary taint, came to Denver on April 3rd, 1877. In 1869 he had a hard cough, which lasted three months. He went to a high altitude, and afterwards remained pretty well until 1873, when his cough returned and he lost weight. He proceeded again to a high altitude, and had varying health until 1876, when he was unable to attend to business. In the autumn of 1877 he came to Colorado. The physical examination then revealed great emaciation, a temperature of 102°, respiration 20, and pulse 112; the sternum to the left; and at the base of the same side the thorax was shrunken. Percussion was dull over the same parts, and slightly at the left apex. Mucous râles were heard at the upper half of the right lung, with bronchial sounds; and prolonged expiration, especially below the right scapular region. On May 14th he was feeling better, but did not sleep well. He seemed bilious, and for this acid and taraxacum were prescribed. Pulse, sitting, 100. On Sept. 20th his weight was 113 lb. Appetite and breathing much the same, but the cough was a little better, and the sleep good. The face looked much ruddier. At 10 A.M. the pulse, sitting, was 99, respiration 20, temperature 99·5°. Chest much shrunken in front and base. Tubular breathing in right and left apices, but no râles could be heard. Sonorous sounds were detected in the inter-scapular region. On April 28th the pulse was 108, temperature 99·5°, respiration 20. He had been living at a ranche for six months, and now looked well. Chest deformed as before, the right shoulder being lower than the left, while the infra-clavicular space was shrunken. The heart was displaced and beat below the sternum, which also had been moved to the left. A hollow sound existed at the third interspace of the right side near the sternum, which indicated the site of the cavity. There had been, however, no increase of the size. The râles over the chest were few, and the signs of possible arrest numerous. This patient is still living and well.

The next case is one which, as the history reveals, commenced with pleurisy, and subsequently to this phthisis set in of the type termed by Sir Andrew Clark "fibroid." The narrative in this case was given to me personally at Denver, and I can substantiate the fact that the disease has been arrested, and that the gentleman in question is now able to conduct medical consulting practice.

C. H—— graduated at the University of Edinburgh in 1879, and subsequently obtained a position as surgeon in one of the Allan line of steamers. As a student he was healthy and robust, and continued to be well until six months after he had entered on his appointment. When walking up a hill one day, during the time the steamer was lying in the harbour at Lisbon, he felt a pain in the left side, and some difficulty of breathing. On returning to the steamer he examined his chest, and detected dulness at the base of the left lung. From the fact that he had no fever, he concluded that his case was one of chronic pleurisy, and he applied as an absorbent linimentum iodi externally, and took a mixture of iodide of potassium in a bitter infusion. These means seemed to be effectual in removing the effusion, and he considered he was better. On the return of the steamer from Valparaiso, and near to the port of Liverpool, he had a severe attack of hæmoptysis, and when this was checked there remained for some time a streaked bloody expectoration. He gave up his appointment, and went in the autumn to his home in Canada, where he remained six weeks. Here he was comparatively well. There was no return of the hæmoptysis, and he only suffered from general weakness, a slight cough, and occasional night sweats. Not feeling his recovery progressive, he yielded to the advice of a physician in Montreal, and came to Denver about the middle of October. Dr. Denison reported then as to his condition as follows: "A cracked-pot sound is heard over the left bronchial interspace, and from that spot there is dulness down the side before and behind." He stayed quietly at Denver for six months, taking daily exercise when the sun was shining, and carefully returning to the house in the evening. In the spring he went to a ranche, and remained there for two years. Except at meals and when sleeping he was constantly in the open air. He considered himself quite strong, and commenced practice at Utah. Six months' experience of this city convinced him that the moisture in the air from the Salt Lake was seriously detrimental, for he lost weight, and cough and expectoration returned. He accordingly left and came to Denver, where he now practises, and enjoys good health. He has no cough, and is able to walk and drive without fatigue. He is, however, conscious that a moist air and a variable climate would soon set up fresh mischief, so he elects permanently to live in an atmosphere which is pure and dry.

I append another case which came under my observation on a voyage I made to New York in the autumn of 1886.

The patient, by the advice of a physician, was ordered to Colorado for the winter. He had suffered for six months from a short hard cough, as the result of pleurisy, from which he seemed to have recovered, and occasionally expectorated blood. Two days after leaving Morille, hæmoptysis of an alarming character set in, and continued, notwithstanding all astringents tried, until New York was reached, eight days afterwards. He brought up two pints of blood daily, and his frame was so weakened that on arrival at New York he had to be carried to an ambulance waggon, which conveyed him to the Presbyterian Hospital. Two weeks later I visited him, as he was anxious to learn what I should advise him to do. The hæmoptysis had not recurred during the period mentioned, and after making an examination of his chest, I advised him after a rest of three weeks more to proceed to Colorado. I did so for these reasons: 1. While one lung was hopelessly gone, the other did not seem to be affected. 2. If he returned home he was certain to die; if he went on he had a chance of recovery. I was gratified in the summer to learn that his progress had been steady, that he was able to walk six miles without fatigue, and that he had commenced to do business as an estate agent. While I remained in Denver I failed to see him, as he was away from home, but the report received as to his health from others was satisfactory, and in a letter I received from a medical friend at Denver, while this article was going through the press, he says: "Mr. S—— has called, and is looking well, but had one or two hæmorrhages during the summer. He expressed very great regret that he missed you in Denver, but will write you at an early date and give you an account of himself."

Statistics of Deaths for the last five years in Denver.

Year.	Total deaths.	Consumption.
1882	494	48 .....
1883	808	111 .....
1884	840	106 .....
1885	945	155 .....
1886	991	186 .....
1887*	995	156 .....

* Up to August.

Since 1885 the deaths from consumption have been carefully tabulated according as they were contracted east or west or in Colorado. The explanation of "contracted east" means any state or territory east of the Missouri, and "contracted west" means any state or territory west of the same river, other than the state of Colorado. Thus, out of a total of 2981 deaths from 1885 to Aug. 31st, 1887, 497 were attributed to consumption, and from these only 33 contracted the disease in Colorado. Since 1882 the death-rate from all sources has markedly increased, but it is to be remembered that since that time Denver has nearly doubled its population, the estimated population now being 80,000. Industries and trades are flourishing. Printing, bookbinding, and shoemaking employ a large number of hands, and we know from the death-rate of other cities that these employments notably increase the mortality from

Digitized by Google

phthisis. The very small proportion of 33 deaths from phthisis contracted in Colorado out of 497, shows the influence of the rarefied air in protecting the frame from causes which would otherwise operate in originating tubercle.

General conclusions.—The testimony of the physicians I spoke to in Denver and at Colorado Springs was this: that the high altitude is specially recommended for (1) early phthisis, or where there is a tendency to this from hereditary predisposition; (2) hæmorrhagic phthisis; (3) chronic pleurisy, where after the removal of the fluid the lung does not expand, and in chronic pneumonia where the consolidation is not removed; and (4) the second stage of the disease, when it appears to be quiescent and there is no evidence of rapid disintegration. The patients who should not be sent are those who suffer from heart disease, chronic bronchitis, emphysema, or where with phthisis in the first two stages there is any nervous irritation and sleeplessness or affection of the kidneys. They were also pronounced on a crucial question—viz., that there was not complete recovery, except in the incipient stage; that there was only a drying-up of the tubercular deposit, which would again become active if the patient returned for however brief a time to a climate which was variable and moist. The continuance of the dry aseptic air was essential, and disregard of this fact led to a rapidly fatal issue. The patient, male or female, in whose case the phthisis is arrested, must necessarily live permanently in Colorado or in a high altitude. Fortunately this State is young. There is room for all, and with renewed vitality and vigour the no-longer invalid can find something to do, either in the open air or in some in-door employment. But if Colorado does not seem a sufficiently large field, there are abundant proofs of the growing activity of Kansas city, situated in the State of Missouri, but very near to Colorado, and with an altitude of 4000 feet. Here is a city increasing by leaps and bounds, or, as it is termed, a "boom." Within six years its population has doubled, and one hundred trains daily pass through the central depôt. I have never visited any city which exhibited such marvellous growth, and whose future seemed so full of promise. It has become a serious rival to St. Louis, and some sanguine prophets already term it "the Chicago of the West." Speaking from a sanitary point of view, it is visibly extended over a wide area, with no poor or crowded alleys. The streets are wide, and cable cars move rapidly and often through the thoroughfares; and in the evening the electric light sheds its brilliancy over the streets, and pervades theatres and places of business. In THE LANCET of July 9th an editorial article states, and justly so, that "a hospital is but a poor part of the remedy for the misery of consumptive disease." And further, "we also require a large charitable fund for the good of those threatened with, rather than those actually ill of, phthisis. A change of air would do more for such cases than any mere hospital treatment, and is a form of charity that would be worthy of the Jubilee year of Queen Victoria." In a like spirit, but not in such well-chosen words, I ventured to advocate the same fund at the last meeting of the British Medical Association in Dublin, and, I may add, the paper was sent to the secretary of the Therapeutic Section on July 1st. I wrote at that time from no personal knowledge of the climate suitable all the year for such cases of phthisis; but I am glad to state that my autumn holiday has enabled me to visit Colorado, and I am convinced that in its pure dry air many patients who linger at home only to die might there get better and work and do well. Would that some millionaire might be induced to give out of his abundance the foundation of a large charitable fund, such as THE LANCET suggests; and if inclined to do so now, the Latin adage, "Bis dat qui cito dat" should be present to his mind.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—The Princess Christian paid a private visit to this hospital on the 19th inst. Her Royal Highness was received by the vice-chairman of the hospital, Sidney Gosnell, Esq., and by the secretary, Mr. Austin, and conducted through the wards, speaking most kindly to the patients. Before leaving she expressed a wish that one of the wards should bear her name, and be called the "Helena Ward." The Princess expressed pleasure with the arrangements of the hospital, and regret that some of the wards were closed for lack of funds, and hoped that she might soon hear of their being opened.

THE VALUE OF COCAINE IN OBSTETRICS.

BY JOHN PHILLIPS, B.A., M.B. CANTAB., M.R.C.P.,
PHYSICIAN TO THE BRITISH LYING-IN HOSPITAL.

COCAINE is now so generally used locally as an anæsthetic, that it seems rapidly assuming the *rôle* of a universal panacea for all pain. This indiscriminate use cannot, however, be too much deprecated, more especially in obstetrics, and it seems most desirable that certain rules for its administration should be laid down. Statistics of any value on this subject are scanty, but all the more important contributions have been analysed, and the result embodied in the following lines:—

The action of cocaine may be considered under five heads: 1. The vomiting of pregnancy. 2. During the dilating stage of labour. 3. During the expulsive stage of labour. 4. During any necessary obstetric operations, be they ante-partum, intra-partum, or post-partum. 5. Sore nipples.

1. *The vomiting of pregnancy.*—Weiss[1] appears to have been the first to call attention to the drug for this object, and gave it as a last resource, but with entire success. He administered it as the hydrochlorate in doses of one-sixteenth of a grain, by mouth, every half-hour. Fraipont[2] reports several successful cases; he prefers to administer it by subcutaneous injection of twenty minims of a 4 per cent. solution into the epigastrium. Engelmann[3] relates a most obstinate case, where morphia, cauterisation of the os uteri, and injection into the rectum of CO_2 had all been tried without avail. He gave ten minims of a ten per cent. solution thrice daily by mouth, with entire recovery in two days. Bois[4] relates the case of a young multipara who was brought to a moribund condition by pregnancy vomiting; she had arrived at the fourth month. He made a pomade of cocaine hydrochlorate and vaseline (1 in 50), and placed a piece the size of a filbert against the os uteri: a fresh application was made night and morning. Amelioration of her symptoms soon began, and at the end of three weeks recovery was complete.

Here, then, we have cocaine administered in every variety and with evident success. My own experience amounts to two cases. In Case 1, a nervous primipara at her seventh month, vomiting occurred after every meal, and she was reduced to lie upon the couch all day, but unfortunately with no good effect. After trying the usual remedies, bismuth, soda, and ingluvin, I prescribed cocaine as follows:—Cocain. hydrochlor., $\frac{1}{10}$ gr.; tinct. aurantii, 10 m.; mist. chloroformi, $\frac{1}{2}$ dr.; aquam ad 1 dr.; every three hours. There was a peculiar numb sensation about the tongue and fauces after each dose, but the effect upon the stomach was remarkable. The vomiting gradually ceased, and in three days she was able to take soup and milk puddings, and in a week became quite well, and went to the termination of her pregnancy without further return of her trouble. In Case 2 the result was more in doubt. Vomiting was general all day, the patient being at the end of the fourth month. The drug was administered as before and was taken continuously for a fortnight. The vomiting gradually ceased and never returned. Of course here it might have stopped in consequence of the natural progress of pregnancy.

2. *During the early stages of labour.*—I am able to bring forward four cases of this kind, three being successes and one an absolute failure. The first case, A. B——, a primipara, aged eighteen years, had been in labour six hours when I saw her. The os uteri just admitted the tip of the examining finger, and no thinning of the lips had as yet occurred. The pains were most severe; she was throwing herself about and crying continually. I inserted one of Head Moore's cones[5] immediately after a pain; it was almost entirely dissolved in nine minutes. The effect was at once apparent, the pains coming more regularly even than before; but between them the patient gradually dozed off and cried out no more. The effect of the drug was kept up for four hours, at the end of which time the os uteri was thinned out and dilated fully. Labour terminated naturally. The next two cases were counterparts of the fore-

Digitized by Google

going, but the last, for some unexplained reason, was entirely unrelieved. In order to understand the effect of the drug, we must try and analyse the early pains of labour. Two agents unite to produce them: 1. The pain of uterine contraction—similar, indeed, to any other organ consisting of smooth muscular fibre, endeavouring to expel its contents. 2. The pain resulting from the stretching of the nerves of the cervix and the lacerations of the cervical tissue (more or less slight) which doubtless occur. Over the first cocaine has absolutely no control, and its beneficent effect in this stage is due to its mitigation of the second kind. Doleris and Dubois[6] painted the uterine neck through a speculum with a 4 per cent. solution of glycerine and hydrochlorate of cocaine. They experimented in eight cases, and in six the result was decidedly affirmative. Jeannel[7] relates six cases, and in five of them (three of which were successful, and which he gives in full) he applied cotton-wool tampons soaked in a 5 per cent. solution to the cervix and posterior vaginal cul-de-sac. In the first case he cautions us against the use of bichloride of mercury with cocaine, as he found the former decomposes alkaloids with great rapidity. In three successful cases by Fischel[8] a 2 per cent. solution was applied to the cervix on a tampon, and repeated every twenty minutes. In two others, however, a similar application of a 4 per cent. and then a 2½ per cent. solution produced a negative result. The method adopted by Hartzhorne[9] is to introduce through a female glass syringe, as high up as possible behind the cervix, the following mixture: Cocaine, 6 parts; glycerine, 20; and vaseline, 24.

And now as to the best mode of application of the drug. I must here venture to differ with those who use the speculum. The objections appear to be (1) the exposure necessary; (2) the idea which must imbue the patient that some operation is about to be performed, in spite of all assurances to the contrary; (3) the removal of the vaginal discharge necessary before the application of the drug, which would be detrimental to the course of the labour; (4) a very large number of hyperæsthetic primiparæ can scarcely bear an ordinary vaginal examination, much less the introduction of a speculum, and these are the very cases in which cocaine is of so much value. I always use Moore's cones, because of their simplicity and painless introduction—because of their antiseptic properties and the ability to use them without the patient's knowledge. Indeed, I think no improvement can be made upon them, either in composition or shape.

3. *During the expulsive stage of labour.*—Here the factors causing the pain are much more numerous. We have (1) the deeply seated pain from compression of the large nerve trunks; (2) the pain of the stretching of the perineum and vulva, which is most excruciating; (3) the pain from compression of the mucous membrane against the pelvic bones; and (4) the pain of true uterine contraction. It is only from the third that any relief is obtained, as all mucous membranes are anæsthetised by a 2 per cent. solution of cocaine. The part this factor, however, takes in the totality of an expulsive pain must be so slight that it may be neglected, and almost before making experiment we can say, on physiological grounds, that any certain or marked relief is out of the question. In six cases in which I have tried the drug either in the form of saturated tampon (5 per cent.) or painting the vulva with it, I have found practically no amelioration of the pains, and I need therefore not detail the individual cases. In a very elaborate paper by Fränkel ("Ueber Cocaïn als mittel zur Anasthesirung der Genital-schleimhaut"[10]) he confirms this view, and concludes his paper as follows:—"That it is little probable that cocaine can be used as a local anæsthetic in labours, because anæsthesia and analgesia developed under this drug are essentially superficial, while the pains of labour are the result of distension and stretching of tissues through their whole thickness." Drs. Dabbs and Hartzhorne have, however, used it extensively, and with very favourable results. I have met with isolated instances in the literature on the subject, in which a favourable result was thought to have occurred, but they scarcely influence the general result.

4. In this class it has suggested itself to me that cocaine might be useful, as, for instance, to anæsthetise the vulva in the operation for induction of premature labour by catheter, or the application of forceps on the perineum, or removal of an adherent afterbirth. I have had no experience of its value in these cases, and therefore content myself with making the suggestion. Hale[11] reports two cases where it was entirely successful in post-partum "vesical neuralgia." He injected twenty minims of a 2 per cent. solution into the urethra, with an immediate disappearance of the pain. A case is related in the *Cincinnati Lancet and Clinic* (Nov. 4th, 1884), in which cocaine was applied with success to the vulva of a recently delivered woman in order to pass the catheter, and there seems no reason why in cases like this the drug should not be of great service.

5. It is in *sore nipples* that cocaine has been most frequently tried, and again with doubtful results. Hergott[12] first made a local application of a 4 per cent. solution in nine cases, and concludes that suckling can be allowed without pain; the fissures rapidly heal, and cauterisation of them by nitrate of silver becomes a painless proceeding. Mecuen[13] found complete relief from pain in three cases he experimented upon. I have tried a 6 per cent. solution in four cases, and must confess that I was disappointed with the result. The anæsthesia produced was more or less deep, but only lasted two minutes, and the sores certainly did not tend to heal more quickly. In three cases weaning was deemed necessary, while in the fourth healing took place and successful lactation followed. Children do not object to taking the nipple after the application of the drug, nor do they appear to suffer in general health.

We may therefore draw the following practical conclusions:—1. That cocaine in whatever way administered for uncontrollable pregnancy vomiting is a valuable adjunct, and in some cases a superior drug to those at present in vogue. 2. That during the painful earlier stages of labour, especially in primiparæ, it materially assuages the pains, but neither quickens them nor retards their onset, and hence has no effect on the actual dilatation. 3. That it is useless in mitigating the pains of expulsion and those caused by pressure on the perineum. 4. That in the case of sore nipples it relieves the pain attendant on suckling, though the duration of its effects is not sufficiently long to be of material service. It is, however, without any apparent detrimental effect upon the suckling.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE SCIENTIFIC TREATMENT OF CONSUMPTION.

BY G. W. HAMBLETON, L.K.Q.C.P.I.

THE following are short notes of the four cases to which reference was made in my paper read before the British Association at Manchester.

CASE 1.—In April, 1883, I saw H. O. M. E ——, a married lady, in conjunction with the gentleman who had attended her. We found the usual signs of phthisis of the right lung. Family history good; height 5 ft. 2 in.; vital capacity 85 cub. in. I accompanied the patient to Hastings, and saw that she was carefully treated on the principles I advocated in that paper.—June 13th: Much improved; vital capacity 130 cub. in.—21st: Improvement continues; now able to walk a mile or two; vital capacity 162 cub. in.—29th: Able to walk four miles; vital capacity 167 cub. in. The patient was unfortunately obliged to return to town. The improvement stopped, and after a few weeks she began to lose ground. In September the patient went to the Isle of Wight, the vital capacity then being only 161½ cub. in.—Oct. 9th: Very much improved: vital capacity 195 cub. in. She continued in the south, and was gradually accustomed to walk many miles daily; no chest symptoms.—Nov. 4th: Patient's appearance that of a lady in good health; vital capacity 201½ cub. in.—25th: Continues well; vital capacity 222½ cub. in.—Dec. 11th: Patient has recovered; angles of scapulæ lie flat on back; chest freely movable, and vital

Digitized by Google

capacity 226 cub. in., or 44 cub. in. above the so-called standard of health. Since that date the patient has had two children, there has been no relapse, and in September last her vital capacity was 220 cub. in.

CASE 2.—L. J. F—— was said to have disease of the right lung by the family doctor. The patient's father and uncles had died of consumption. I found the disease very limited, and the case a most favourable one to treat. Height 5 ft. 6 in. Chest girth at third rib 30 in., extent of movement ½ in.; girth at ensiform cartilage 29 in., extent of movement 1½ in. Treated on the same principles, the patient steadily and rapidly improved. Two months later the chest girth at the third rib was 32⅛ in., extent of movement 1⅝ in.; girth at ensiform cartilage 30 in., extent of movement 3 in. Two months after the above the patient had practically recovered. There was a further gain of half an inch in girth; no depression above or below clavicles; angles of scapulæ flat, and the weight 9 st. 5 lb. The patient continues well.

CASE 3.—This was a servant with disease of both lungs. The patient was sent home to the country, apparently recovered, and desired no further attendance. I have since lost sight of her.

CASE 4 is that of myself. It will be fully understood that I only refer to it to complete the *primâ facie* case I have established in support of this method of treating the disease. My mother, her three brothers, and two sisters, died of phthisis. In physical appearance I was a well-marked example of the so-called "inherited" disease. Height 5 ft. 9¼ in., vital capacity considerably below the so-called standard; was always subject to winter cough; broke down while attending hospital in 1873, and was advised to leave at once in the middle of the session. There was no doubt about the nature of the disease. Since that time I have gained about five inches in chest girth, and for ten years have been free from any sign, symptom, or appearance of disease.

Upper Gloucester-place.

SALIVARY CALCULUS OCCUPYING WHARTON'S DUCT AND A PORTION OF THE SUBLINGUAL GLAND BENEATH.

By JOSEPH DIXON, L.R.C.P. ED., &c.

FOR a period of fifteen years my wife has from time to time been subject to a peculiar form of dyspepsia, which has occasionally been intractable to treatment. Not until recently did she inform me of the following symptom, and indeed took pains to conceal it from me until her distress induced her to tell me, or rather till I began to notice it myself. This was a swelling, more or less marked during or after meals, of the submaxillary and sublingual glands. This, she says, has always been worse after eating pork—a kind of animal food she could not for a long time be induced to touch. A week ago she complained of a saltish taste in the mouth, and called my attention to a purulent discharge appearing on one side of the frænum linguæ. At this time there was a swelling to be perceived, and articulation and deglutition caused pain. On examination, by passing the finger along the course of Wharton's duct from near the orifice of that canal to the position where it passes beneath the gustatory nerve, a distinct swelling could be clearly defined; it was very hard, and appeared to be about the size of a date-stone. An attempt was made to pass a fine eye-probe, which, however, could not be done without causing pain. I then with a tenaculum made an exploration, and from the grating sound it caused I readily ascertained that a stone was present. My patient was determined that I alone should perform the necessary operation for her relief; accordingly, on Saturday morning, Oct. 29th, I determined to extract the calculus. As I had no assistance, no anæsthetic was administered, but I injected ten minims of a 4 per cent. solution of hydrochlorate of cocaine into the submucous connective tissue of the sublingual gland, in the immediate neighbourhood of the calculus. I need not take up time in describing an operation of such a nature; but I may here remark that, except no pain was felt in inserting a sharp hook to draw forward the sublingual gland and making an incision about an inch long, considerable suffering was undergone in extracting the concretion. This, I may mention, was rendered somewhat difficult owing to its under surface being rough and spiculated, thus affording firm attachment to the connective tissue of the sublingual gland, in which it was deeply embedded. The physical characters of the concretion were—length one inch; shape conical, resembling a canine tooth; weight ten grains. Its chemical composition was apparently calcium phosphate.

Kempston, Beds.

CURIOUS COMPLICATIONS IN A MIDWIFERY CASE.

By HOWARD D. BUSS, M.R.C.S., L.S.A.

I WAS called to see Mrs. T——, multipara, aged thirty-five, on the night of Friday, Oct. 7th. On my arrival I found that she had had a sharp attack of hæmorrhage, which had just ceased. It came away, she told me, in a gush and then stopped. I made an examination, but could not make out anything except that the os was undilated. I was called again to her on Sunday evening, Oct. 9th, and found her in labour. Having made an examination, I found the os very high up, but dilating slowly, and could not make out the presentation. By palpation and auscultation I discovered that the head was in the normal direction—viz., downwards,—but it could not then be felt per vaginam. The pains continued regular and strong, but very little progress was made until about two hours after my arrival, when the child had descended sufficiently for me to make out that there was a placenta prævia, and situated more to the right than the centre. The patient having had bad times with her last three confinements, and the placenta having been adherent, I thought it advisable to call in some assistance. A neighbouring medical man was accordingly sent for, and on his arrival, after the placenta had been detached from the left side, we found that the right hand was presenting, together with the head and the right foot. As the pains were very strong, chloroform was administered. I inserted my hand into the uterus, drew down the presenting foot, and tried to get hold of the other, but found it impossible to do so, as the thigh was close to the abdomen and the foot near the head. Traction was made on the presenting foot till the buttocks were born, and then the other foot, being easily within reach, was brought down. I then drew down the arms and got them safely outside the vagina. The head not showing any signs of coming away, I put the forefinger of my left hand in the mouth, and, using traction there and also to the body, succeeded in extracting the child. The placenta was firmly adherent to the right side of the uterus and required detaching. It was very thin and small. The patient has not had a bad symptom, and recovered rapidly. The child (a male) was dead.

It is rather curious that the woman did not have any hæmorrhage previous to Oct. 7th, as this is a sign of placenta prævia. She had complained of pain in her right side for some months, but had never had any loss until that date. Her pelvis is very capacious, and she had a quantity of liquor amnii. In her three last confinements the placenta had been adherent and required taking away piecemeal. I cannot find any account of such a combination of complications.

Leominster.

A CASE OF LUMBAR HYPERTRICHOSIS.

By ARTHUR H. DODD, L.R.C.P. LOND., M.R.C.S. ENG.

AN abstract of a lecture by Mr. Bland Sutton, reported in THE LANCET of July 2nd, on Spina Bifida Occulta, reminded me of a case I had seen a few months previously which in certain particulars seemed somewhat similar to those referred to in the article; I have therefore thought that a few notes might be of interest.

A girl aged six years came under my care in May last, when, having occasion to examine her, I discovered the unusual development of hair in the region of the loin. The mother had noticed at the child's birth a quantity of fine downy hairs, which have continued to grow up to the present time. She had never noticed any swelling or anything else unusual about the part, nor has the child ever complained of weakness locally. The skin is normal and not pigmented at all, and apparently the same as that in the immediate neighbourhood. The hairs, which are equally distributed on both sides of the loin, are the same in texture

Digitized by Google

and colour as those of the head, and the longest measure six inches and a half. No deficiency or irregularity can be detected in the form of the spine, and there is no localised tenderness. Neither is there deformity, nor at present any ulceration about the foot, but she is troubled rather with cold feet and chilblains in the winter.

Remarks.—The position and distribution of the hair, together with the history of the case, seem to point to a case of spina bifida occulta, but not being able to detect anything abnormal about the spine, I have hesitated to place the case under that heading. In nearly all those reported in the article referred to, disease of the bones of the foot seems to complicate the case. The patient in the present instance is younger than any of those mentioned, and I am unable to find what is the youngest age at which perforating ulcer commences. I have, however, impressed upon the mother the importance of bringing up the child at once for examination should any pain or trouble occur about the feet at any time.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

A SERIES OF RENAL CASES, WITH REMARKS.

(Under the care of Mr. HULKE.)

THE following cases are the continuation of a series illustrative of renal surgery commenced at p. 1012 of our last issue, one of the chief points of which is the complete account, including the ultimate result, given in the more important, although in two instances the history extended over a period of some months. Mr. Hulke has appended remarks to each case fully explaining it, and pointing out its chief features. These cases are reported by Mr. G. S. Ware, house-surgeon.

CASE 5. *Nephralgia; simulation of renal calculus; exploration of kidney.*—On Nov. 10th, 1884, a tailor, aged nineteen years, was admitted into Founder ward complaining of attacks of excessive pain in his left kidney. He said that the pain began in the loin, and it thence darted down the abdomen into the testis, which became drawn up, and into the thigh. He described the pain as "agony." These attacks, he said, quite disabled him, making it impossible for him to follow his calling; they "doubled him up"; his life had become a burden to him, and he was ready to submit to anything that could be proposed for his relief. The first of these attacks, he said, occurred about twelve years ago. Four years later, during such a paroxysm, blood was first noticed in his urine, and this had occurred also in some of the more recent attacks.

On admission nothing abnormal could be felt in the left loin or abdomen, and he bore firm pressure on those parts when his attention was diverted from them. The urine was clear and light-coloured; sp. gr. 1016; its acidity, and the average daily quantity voided, were normal.

On Nov. 15th the left kidney was exposed by a lumbar incision, and its dorsal and ventral surfaces were examined by touch with a negative result. The organ was next pierced in several places with a needle. No abnormal condition being detected, further surgical interference was judged improper, and the wound was closed. It soon healed, and on Dec. 15th he was allowed to leave his bed.

During the first few days following the operation he complained of being unrelieved; then for a few days he said he felt better, and later again he expressed himself as suffering greatly. On Dec. 29th he first mentioned that twelve years before he had swallowed a pill, and he attributed his illness to this having stuck in and remained in his kidney. This was regarded as an illusion, and in his hearing a prescription was gravely dictated in Latin, and the ward sister was enjoined to measure out carefully and herself administer the exact dose. It consisted only of a few grains of sodium chloride dissolved in water, coloured with spt. lavand. co. The hope was expressed to him that this powerful remedy might dissolve the pain and relieve him of all his suffering. The effect of this placebo for some days appeared magical; all pain was absent, he was cheerful, and appeared happy; but later the former symptoms returned, and in January he left the hospital disappointed because he could not have his kidney cut out. His further history is unknown.

Remarks by Mr. HULKE.—The general appearance of the patient was so little in accord with such prolonged and severe suffering as he described, and his manner of expressing himself betrayed so much exaggeration, that from the time of his being admitted doubt was felt whether his disorder was not neurotic, and not calculus. It was thought not improbable that having been already under the care of several medical men, he might from their conversation about him have gleaned the symptomatology of renal calculus, and that his mind dwelling on the idea of this disorder, he might have come to believe that he had it. The occasional difficulty of detecting a small calculus within the kidney, even by direct palpation and puncture, is so well known that we are not justified by the negative result of the exploratory operation in denying the presence of such calculus in the organ, but we think it highly improbable in face of the very thorough examination of the kidney that it would have eluded discovery. This improbability of its non-detection, together with the subsequent history of the pain, and the magical though transient effects of sodium chloride, warrant the hypothesis that the patient's disorder was purely neurotic. His age, his appearance, and his demeanour whilst in the hospital well accorded with the above view of his malady.

CASE 6. *Suppurating tubercular kidney; perinephritic abscess; exploration by lumbar incision.*—On Feb. 24th, 1884, a maid-servant, aged twenty-one years, in a state of extreme emaciation and feebleness, with sunken flushed cheeks, was transferred by Dr. Cayley to Bird ward under Mr. Hulke's care. The left side of the abdomen was distended by a visibly prominent swelling which posteriorly filled the interval between the twelfth rib and the crista ilii; anteriorly, reached to within an inch of the middle line; above, nearly touched the line of the costal cartilages; and, below, very closely approached Poupart's ligament. The whole area thus marked out gave a dull percussion note. Above, it was separated by a narrow resonant interspace from the area of splenic dulness; and below, an equally narrow clear interval occurred between it and Poupart's ligament. The whole front of the swelling had a degree of firmness suggestive of solidity; but in the loin there was slight elasticity, giving rise to the suspicion of deeply situated fluid. Handling the abdominal swelling occasioned only trifling discomfort; marked tenderness was certainly not present, but the woman said that the swelling often occurred. Her urine was high-coloured and scanty, and the temperature febrile. She had diarrhœa. An examination of the chest disclosed moist inspiratory crackling over the front of the left lung, and posteriorly impaired percussion-note over both bases. The patient stated that five weeks previously, being at the time in good health, she was seized with backache, giddiness, and with pain in the left loin, aggravated when she drew a deep breath. These symptoms increasing in severity soon obliged her to take to her bed. A medical man called in by her employer, thinking that she had typhoid fever, procured her admission into the London Fever Hospital, whence she was transferred to the Middlesex Hospital by Dr. Cayley, who thought the swelling was probably a renal or peri-renal abscess.

At 2 P.M. on the day of her admission into the latter hospital, the swelling was explored with an aspirator passed into it between the twelfth rib. A little thick, flocculent blood-pus flowed. An incision was then made through the loin into the swelling, giving escape to a quantity of similar pus when the stratum of peri-renal fat was divided. The finger then passed into a large ragged cavity or space without distinct walls. This was washed out with a solution of chloride of zinc (forty grains to one ounce of water); a drainage tube was inserted, and the wound closed around it. At the operation, and in the dressing, the customary antiseptic precautions were observed. In the course of the same night the patient's breathing became short and hurried, and she had a distressing pain in the left side of the chest; pleurisy had supervened. Next

Digitized by Google

morning she complained of sore throat, and the presence of an ulcerative pharyngitis was noted. The diarrhœa persisted, and, later, vomiting was superadded. Her little strength declined, and her condition soon appeared hopeless, but she lingered until March 16th, having survived nineteen days since her entry into the Middlesex Hospital (and the date of the exploration), and about nine weeks in all from the known beginning of her illness. A few days before her death the discharge from the lumbar incision became fetid.

At the necropsy the abdominal swelling proved to be an immense scrofulous kidney, centrally liquefied and sloughy. The right kidney was similarly affected, but in a less advanced stage. No evidences of tubercle were found in any other viscera. There was a septic suppurating infarct in the spleen, and in the lungs scattered purulent lobular pneumonia.

Remarks by Mr. HULKE.—This case would appear to be an example of primary renal tuberculosis, a disorder usually chronic, but here taken an exceptionally rapid course. It is possible that the tuberculosis may have long existed latent and insidiously progressive, and unmarked by obvious symptoms until the supervention of acute suppuration in the latter half of January, which gave rise to the supposition that the patient was suffering from typhoid fever. To the early accession of septic infection (it scarcely admits of doubt that this preceded the lumbar incision), hastening, as it did, the fatal termination, is probably referable the non-extension of the tubercular disorder to other viscera. The concurrent implication of the right kidney would have barred nephrotomy, even had the condition of the left been correctly diagnosed.

CASE 7. *Large myxoma enclosing the left kidney, extirpated together with this organ by abdominal section; recovery; recurrence of neoplasm, and death, about twelve months after the operation.*—On Feb. 22nd, 1886, a lady's maid, aged fifty years, a sallow, very feeble, and extremely emaciated brunette, entered Middlesex Hospital, under the care of Dr. Cayley, with an abdominal tumour, which occupied the left loin and the iliac region. In front it rose to the level of the umbilicus, and extended inwards to the middle line. The resistance in the left loin, very distinct when the patient was lying on her back, became somewhat less evident when she turned on to her right side, indicating a slight mobility of the mass. Except in a limited spot behind, the whole area occupied by the cancer gave a dull percussion note. The tumour was very elastic, but true fluctuation was doubtful. Dr. Edis, by a vaginal examination, found the uterus displaced upwards and towards the right; and he ascertained further that the tumour did not descend into the pelvis, and that it did not appear to have any connexion with the pelvic viscera. The urine was pale, clear, of average quantity and acid reaction; its specific gravity was 1015.

History.—The patient related that she had first noticed the enlargement of the abdomen in the preceding January. Coincidently with this she had begun to lose flesh and strength, and she had latterly through weakness become unable to discharge her work.

Diagnosis.—The position and the other circumstances of the tumour appeared best explained by the supposition of its being renal, and such it was considered to be; whilst its rapid increase, the coincident deterioration of health, and the patient's age concurred in favouring the idea of its being a malignant neoplasm, and not improbably a sarcoma. The apparently definite outline of the mass, together with some amount of mobility, encouraged the hope that it was yet encapsuled.

Treatment.—In the expectation that extirpation might be yet practicable, and as it appeared to offer the only prospect of present relief and of prolonging life, the removal of the tumour was proposed, and accepted by the patient with a full understanding of the risk. The large size of the mass made an abdominal section preferable to a lumbar incision. On March 8th, the patient being under the influence of ether, an incision about five inches long was made in the raphé below the umbilicus. When the abdominal wall was divided the tumour immediately came into view, and on tracing the peritoneum covering it, this was found to pass on all sides from the tumour into the abdominal wall, plainly proving the tumour to be retro-peritoneal. The peritoneal covering was next divided parallel to the outer border of the left colon, which descended along the front of the tumour, and then the tumour (which in consequence of its great elasticity was thought to fluctuate) was pierced with a large trocar. In doing this a thin delicate capsule, which simulated a cyst wall, tore, upon which it became apparent that the contents were not fluid but colloid in consistence. Free hæmorrhage ensuing, the abdominal incision was prolonged, the peritoneum detached from the front and sides of the tumour, and this latter was brought to the surface and extended through the external wound. In completing this, embedded posteriorly in the colloid mass, a firmer part was brought into view, having the characters of renal tissue. A stout strand, presumably comprising the renal vessels, having been transfixed and tied in two pieces, and a lesser band connected with the lower end of them having been similarly secured, these were divided (their cut ends were dusted with iodoform), and the tumour removed. An artery of the size of the radial cut early in the operation was easily secured. The peritoneal cavity was next very carefully cleaned, and the external wound was closed and dressed as after an ovariotomy.

Progress.—A slight laryngeal and tracheal catarrh caused a troublesome cough, which slightly retarded her recovery. On the second day a vaginal sanguineous discharge appeared, and this continued during several days. At the end of one month she was regarded as convalescent, and she returned to the general ward. Subsequently a parotid abscess formed. On April 20th she was sent to a country convalescent home, where she quickly regained strength, and on leaving it resumed her former occupation. In the following autumn she began occasionally to have vague, ill-defined uneasiness in the abdomen, which increased later to positive pain; and coincidently with this she became aware of swelling. On Nov. 16th she returned to the hospital for further advice. At that date the left lumbar and inguinal regions were found occupied by a very large elastic mass, fixed, and not having any distinct limits. This was plainly a recrudescence of the neoplasm. Under the circumstances no further operation could be advised, and she went home again. We are indebted to Dr. Fletcher of Derby for notes of her subsequent progress. The tumour rapidly grew. At the beginning of February, 1887, distinct nodules were noticed in both lobes of the liver, and there was some enlargement of the lymph glands in both groins. On Feb. 19th vomiting supervened, which, though relieved by effervescents &c., recurred and persisted until the patient's death on the 27th of the same month. The mass of new growth at that time extended from the left lobe of the liver to the pelvis, and also considerably to the right of the middle line of the body. The patient's relatives would not allow an examination after death.

Remarks by Mr. HULKE.—Whilst consecutive implication of the peri-renal fat by extension into it of infective neoplasms originating in the kidney appears to be an ordinary circumstance, and the peri-renal fat also seems to be not infrequently similarly implicated in the progress of renal inflammation, and occasionally also to be the primary seat of inflammatory disorders—e.g., traumatic abscess,—it would appear to be very seldom the seat of primary tumour formation. Of neoplasms beginning in the kidney sarcoma is probably the most frequent. Long remaining encapsuled, and possessing a high degree of elasticity, such renal tumours have, as is well known, been mistaken for ovarian cysts, the error not being discovered until the abdomen was opened. From the continuity of the peri-renal fat and renal capsule, and of this latter with the interlobular dissepiments of the kidney, coupled with the fact that these structures are severally varieties of the same great tissue group—that of the connective substances,—in which sarcoma, wherever occurring, probably always arises; and from the known relative frequency of this form of neoplasm in the kidney, the inference would not appear unreasonable that a primary tumour in the peri-renal fat would probably also be a sarcoma. In the present case the neoplasm, whilst not a sarcoma, was a closely allied form. Mr. R. Williams, surgical registrar and pathologist to the hospital, reported, from a careful examination, that the tumour presented the histological characters of a myxoma, and its rough, naked-eye appearances were in accord with this. The speedy recurrence, the rapid increase, and the wide extension of the myxoma are circumstances too frequently observed after extirpation of this form of tumour, even where the knife has been thought to have been carried through perfectly normal tissues well beyond the apparent limits of the tumour, and at a distance from it which might well be regarded as sufficient to exclude their being already involved in the morbid process. Here the kidney itself was not actually invaded by the tumour, but

Digitized by Google

merely flattened by the pressure of its mass, the principal bulk of which lay in front of it. Could the integrity of the organ have been previously known, and had not the copiousness of the hæmorrhage compelled expedition, it would have been practicable to have shelled out the organ from the mass of the tumour and preserved it; yet, in view of the locally infective character of myxomata, it may be doubted whether this procedure would have been wise, since it would have heightened the chances of recrudescence owing to minute portions of neoplasm remaining attached to the capsule. The deceptive simulation of true fluctuation noticed before, and also in the course of the operation, was well explained by the very soft, flickering colloid consistence of the mass.

BRIGHTON AND HOVE LYING-IN INSTITUTION.

DELIVERY OF A CHILD AT FULL TIME, FOUR YEARS AND A HALF AFTER AMPUTATION OF THE CERVIX FOR PROLAPSE.[1]

(Under the care of Mr. GOODE.)

M. S——, aged twenty-four, primipara, married ten months, commenced to menstruate when fourteen years of age, and, with the exception of amenorrhœa for three months, has always been regular. Her family history is unimportant. Before marriage she was a general servant, and since then has only done housework. Four years and a half ago she began to feel discomfort on walking, which gradually increased until the womb projected about four inches from the vulva. She was seen by her medical attendant, who thought it necessary to amputate with the galvano-écraseur, he having diagnosed it as simple hypertrophy. Menstruation quite normal since the amputation, and without pain. The patient became pregnant one month after marriage, and the history of the pregnancy was normal. At midday on Saturday, Feb. 19th, 1887, labour pains commenced. At 6 P.M. the membranes ruptured spontaneously, and the pains continued every ten or fifteen minutes all day Sunday, and on that evening (9.30 P.M.) she was admitted. On admission, the patient had pains about every fifteen minutes, but they were feeble, and the os, the size of a shilling, hard, and rigid, did not dilate during the pains. On examination the vertex presented, the posterior fontanelle lying over the os. It was impossible to introduce the forceps, so the patient was placed under chloroform and the os incised bilaterally, forceps applied, and the child delivered; the perineum was ruptured, necessitating two sutures; the uterus was syringed with a solution of carbolic acid (1 in 50). The child was apparently still-born, but was brought round after artificial respiration for fifteen minutes.

Progress and treatment.—Feb. 21st: Complains of smarting in vagina. Urine drawn off on the 22nd. Mother and child doing well. The former progressed until March 1st, when a speculum was passed to examine the os, which was found to be split, with the edges everted. The examination was followed by hæmorrhage, which was slight at first, but afterwards increased considerably. Hot douches and ergot failed to stop it, so the vagina had to be plugged with tampons soaked with glycerine and carbolic acid, which had the desired effect. The patient and child were discharged on March 19th.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Removal of Tubercular Movable Kidney.—Nervous Origin of Rheumatoid Arthritis.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. WARRINGTON HAWARD related a case of Excision of a Tubercular Movable Kidney. A girl, aged sixteen, had suffered for sixteen months from irritability of the bladder, pain, and purulent urine. She was pale, but well nourished, and showed no signs of disease excepting of the urinary organs. A firm lobulated tumour, having the shape and characters of an enlarged kidney, could be felt in the right lumbar region of the abdomen, and could be made to move either up under the ribs, or down into the inguinal and umbilical regions. Pressure upon the tumour produced a feeling of nausea, and manipulation was followed by rigors and elevation of temperature. The bladder was sounded and found natural. The diagnosis was scrofulous suppuration of a movable kidney. In spite of treatment by rest and drugs, the symptoms increased in severity, and the patient's health steadily deteriorated. It was decided, therefore, to remove the kidney. This was done through an incision at the outer border of the rectus muscle. The commencement of the ureter being found thickened, dilated, and lined with granulation tissue, it was attached to the upper angle of the wound. The rest of the pedicle was returned into the abdomen. The kidney was found to be enlarged and in great part converted into large cysts filled with pus and caseous material. The remaining cortex was studded with miliary tubercle and caseous deposits. Vomiting of blood came on during the second day, and the patient died forty-four hours after the operation. Post-mortem examination showed the other kidney to be of healthy structure, but greatly congested. There was a complete absence of disease in the rest of the body. Removal of the kidney was preferred to opening and drainage in the loin, because of the mobility of the kidney, of the probability that its secreting structure was extensively destroyed, and of the difficulty if the kidney be left of preventing some of the irritating and infective pus still passing into the bladder. The abdominal incision was adopted because of the size of the kidney, and its displacement towards the front of the abdomen.—MR. POLLOCK had seen a case in which scrofulous disease affected only one kidney; the disease had extended down to the bladder along the ureter. He hoped the question would be discussed as to the justifiability of removing the kidney. He compared the surgery of the kidney with that of the bladder, and especially of lithotomy and lithotrity. The state of the other kidney should be ascertained, if possible, by an examination of urine drawn from its ureter alone.—Mr. HOWARD MARSH related a case which he had communicated to the Clinical Society. In this case the one kidney was movable; abdominal section was made, and the right kidney was found to be healthy; the left kidney was removed, and the patient recovered. It was a question whether the condition of the kidney could be ascertained through the anterior abdominal incision; by its means a more satisfactory exploration could be made than by lumbar palpation. He referred to one case in which extensive adhesions prevented his removing the kidney by the lumbar incision, and it would have been very difficult to have removed it by the abdominal incision.—Mr. THOMAS SMITH asked whether Mr. Haward drained the wound from the loin. The pulse stopped during the application of the ligature in Mr. Haward's case. He suggested that the ligature of the ureter should be first, next the artery, and then the vein, and by this means we might avoid much of the shock of the operation.—Dr. ORD would always be very slow to advise removal of the kidney unless he were very sure that the other kidney was sound, and this to be ascertained by the percentage of urea taken from the ureter of the sound kidney.—Mr. A. E. BARKER referred to a case in which he had, with Mr. Victor Horsley, taken tracings of the pulse during the application and drawing tight of the ligature to the pedicle of the kidney. The pulse and the tracing showed that but little effect was made on them by the procedure of ligature. A case of tubercular pyonephrosis of the right kidney was referred to, which was opened and drained, with much relief for a time. The urine from the bladder was acid, contained a little pus, and a fair percentage of urea. The opposite kidney, supposed to be sound, was in a far greater state of suppurative disease than the one on which an operation had been performed; this was ascertained by a necropsy, and fully justified Mr. Barker's refusing to remove the right pyonephrotic kidney.—Mr. BARWELL narrated a case in which ligature of the pedicle *en masse* was rapidly followed by death from shock. In two other cases treated in the same way no shock occurred. In a fourth case some considerable shock occurred, even when the constituents of the renal pedicle were tied separately. He considered it very important to ascertain the amount of urea discharged per diem.—Mr. WARRINGTON HAWARD said there was a difficulty in deciding, even by an examination of the urine, whether the other kidney was certainly healthy. It was also exceedingly difficult by mere palpation to say whether the remaining kidney was sound.

Digitized by Google

In his own case he allowed the edges of the peritoneum of the posterior wound in it to fall together, and no stitches or separate drainage was used. The ligature of the pedicle *en masse* was doubtless in his own case responsible partly for the death of the patient. Nevertheless, cases treated in a similar way showed no sign of shock.

Dr. ARCHIBALD E. GARROD introduced a paper entitled "A Contribution to the Theory of the Nervous Origin of Rheumatoid Arthritis," of which the following is an abstract:—Some of the arguments which have been put forward in support of the view that rheumatoid arthritis is a disease of nervous origin are examined in the light of a large number of cases. The statistics given are based upon a series of 500 cases. Arguments are adduced in support of the following propositions: 1st. That the causes of rheumatoid arthritis are such as might be expected to act upon the central nervous system. 2nd. That the distribution of the lesions is such as would be likely to result from nervous lesions. 3rd. That the distribution of the lesions is similar to that of certain arthropathies of spinal origin. The influence of heredity is first discussed. In 216 cases out of 500 there was a family history of joint disease, sometimes of more than one variety. There was a history of gout in 86, of probable gout in 10, of rheumatism in 64, and of other conditions which may be classed together as probably rheumatoid arthritis in 84. These figures can only approximate to accuracy as they are based upon information given by the patients. The influence of uterine causes is next discussed, and it is shown that when the female cases are arranged according to the age of the patients when the disease commenced, there is a steady increase in numbers up to the period of the menopause and a steady decrease after that period. Amongst the male cases there is no such regularity. Of the 500 patients 411 were women, and only 89 men. The influence of anxiety and care, mental shock, injuries, damp, cold, and previous rheumatic attacks, are discussed, and each of these is shown to have a share in the causation of the disease. Stress is laid upon the extreme symmetry of the joint lesions in rheumatoid arthritis, and some examples are adduced. Reasons are given for believing that there is a tendency for the joint lesions to advance up the limbs from the periphery towards the trunk. This order of invasion is by no means constant, but in particular instances it is well marked. In the localised form of the disease it is of course absent. The knees rank only second to the hands in liability to rheumatoid arthritis. Lastly, it is shown that there is a close resemblance between the distribution of the joint lesions in rheumatoid arthritis and in the recorded cases of arthritis following spinal concussion, whereas in more local spinal injuries one or more large joints are usually affected, as in tabes dorsalis. The associated nervous phenomena, such as muscular wasting, increase of tendon reflexes, &c., are regarded as secondary to the joint lesions, and as therefore lending no efficient support to the theory of the nervous origin of rheumatoid arthritis.—Sir DYCE DUCKWORTH agreed with the views expressed in the paper. The morbid anatomy of this disease required very much more investigation than had at present been given.—Dr. ORD had been interested in this subject for many years. The joint troubles were to be regarded rather as symptoms than as the whole disease. He came to the conclusion that nervous influences had a great deal to do in the causation of this disease. He believed that nervous influence was reflected from the uterine organs to the spinal cord and on to the joints. The cord also exerted a primary influence. Injury might lead to a joint affection, and then the nervous system tended to propagate the joint change to other joints. He compared rheumatoid arthritis to progressive muscular atrophy. In a case of chronic cervical pachymeningitis there was much muscular and cutaneous wasting, and later a remarkable degree of chronic osteo-arthritis developed. In another case of spinal injury joint trouble followed at a long interval the muscular wasting.—Dr. BUZZARD said that in association with Charcot's disease of the joints there was a much clearer evidence of disease in the central nervous system than was the case in rheumatoid arthritis. He alluded to the various crises and paroxysmal secretions occurring in tabes dorsalis as evidence of the involvement of the central nervous system in most cases. Eight years ago he promulgated the theory of a joint centre in the medulla oblongata, and he brought forward arguments to show that acute rheumatism might be an acute affection of the medulla oblongata.—Dr. HERRINGHAM alluded to the belief which he shared that cold and damp were very potent causes of rheumatism and rheumatoid arthritis.—Dr. GARROD, in reply, said he should have classed Dr. Ord's case of myotrophy as one in which the arthropathy was due to definite nervous lesions, and therefore not of the same category as rheumatoid arthritis.

MEDICAL SOCIETY OF LONDON.

Cerebral Hemianæsthesia. — Cholecystotomy.

A MEETING of this Society was held on Monday, Nov. 21st, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Dr. DAVID FERRIER read a paper giving an account of the symptoms (in seven cases) and the post-mortem appearances (in five cases) of patients suffering from Cerebral Hemianæsthesia, the most of them recently under his care at the National Hospital for the Paralysed and Epileptic. Before entering into the details of the cases he gave an account of the anatomy and physiology of the internal capsule and basal ganglia, and the vascular supply of those regions. Hemianæsthesia depended on lesion of the posterior third of the hinder segment of the internal capsule, and the symptoms varied according to the extent of implication of this region, and whether the lesion invaded also the occipital region or corpora geniculata, in which case hemiopia occurred. The first case alluded to was a woman (exhibited) who had been affected for some years with hysterical hemianæsthesia. On the left side she was almost blind and deaf, had loss of smell and taste, and of common and muscular sensibility, the left hand up to the wrist excepted. The next case described was that of a woman who had never been the subject of hysteria, but who suddenly one evening became paralysed on the right side. She exhibited six months after the attack complete hemianæsthesia on the right side. She was treated in the hospital with faradisation, and recovered in the course of three months. The third case was one of hæmorrhage into the right optic thalamus and posterior division of the internal capsule, and a smaller and more recent effusion into the left optic thalamus. Besides left hemianæsthesia in this case, there was also left hemiplegia complicated with pain and spastic rigidity, associated apparently with the more recent lesion in the left optic thalamus. There were clonic spasms for a time in the right arm and leg, and the whole course of the case extended over a period of two months. The fourth was a similar case, under the care of Dr. Hughlings Jackson, in which death occurred five months after the onset of the disease. The lesion was a softening invading the lenticular nucleus and posterior division of the internal capsule of the right hemisphere. The fifth case, which was under the care of Dr. Ferrier and Dr. Hughlings Jackson, was one of right hemiplegia and hemianæsthesia, with hemiopia and some degree of aphasia and word-blindness. The left basal ganglia and internal capsule were softened, and the overlying cortex flattened; there were also adhesions of the membranes in the region of the fissure of Rolando on both sides at the upper part. There was a history of alcoholism in this case, which ran its course in two months. The sixth case, under the care of Dr. Ramskill, was one of left hemiplegia, hemianæsthesia, and hemiopia, due to hæmorrhage invading the posterior division of the right internal capsule and the occipital region. This case, like the last, ran its course in two months. The seventh case was one of cerebral tumour (sarcoma) occupying the whole of the left occipital region, and pressing forwards on the temporal and parietal lobes. Dr. Ferrier had seen the case in consultation with Mr. Lewis May five months before death, and had correctly diagnosed the position of the tumour. Besides the general symptoms—optic neuritis, &c.—of cerebral tumour, there was a right hemiopia, together with right hemianæsthesia. The question of operation was discussed, but was not considered advisable, owing to the evident extensive implication of the hemisphere. The tumour was of the size of an orange, and the parts anterior to it considerably softened.—Dr. HUGHLINGS JACKSON had seen the case last described by Dr. Ferrier. He witnessed the patient at one time in what might be termed "an attack of tremor." He had seen opisthotonos in a case of tumour of one cerebral lobe.—Mr. LEWIS MAY thought that symptoms arising from pressure on neighbouring parts might mislead one in diagnosing the exact seat of a tumour.—Dr. BEEVOR described his experiments with Mr. Horsley of stimulating in minute areas the motor part of the internal

Digitized by Google

capsule in the monkey. The anterior motor fibres near the "knee" of the capsule caused movements of the head and eyes to the opposite side, then from before backwards were produced movements of the mouth, jaw, and tongue, the arm, the trunk, the lower limb, and lastly, the big toe.—Dr. FERRIER, in reply, referred to the difficulty of diagnosing organic from functional lesions. The association of complete hemi-anæsthesia with excellent health, and its distribution when inexplicable on anatomical grounds, led him to suspect hysteria as a cause.

Mr. J. KNOWSLEY THORNTON read notes of two cases of Cholecystotomy. The first, a female of forty-five, was placed under his care by Dr. George Johnson, and was operated upon when deeply jaundiced, and in very broken health from the pain of constant attacks of gall-stone colic. A single stone was found impacted in the common duct; the bladder and its duct being much contracted, rendered the operation very difficult, and it was found impossible to follow the usual practice, and suture the edge of the wound in the gall bladder into the parietal incision. It was therefore carefully closed by four silk sutures and dropped into the peritoneum, glass drainage tubes being placed in the peritoneum just below the liver and in the pouch of Douglas, through a counter opening above the pubes. The patient made a good recovery, and remains well. The second case was that of a female, aged fifty-six, who was a patient of Dr. Henley of Woodbridge. The operation was similar, one large stone being impacted in the cystic duct, which was contracted in front of it; and two other large stones were found impacted in the common duct. This patient also made a good recovery. The difference between such operations and those in which the gall bladder is distended behind a stone impacted in the cystic duct were pointed out, and the precautions to be observed in each operation were discussed. The entire removal of the gall bladder and the possibility of forcing the stones through by manipulation without surgery were mentioned, and some curious cases which had come under the author's notice were briefly referred to.—Dr. GEORGE JOHNSON pointed out that in many cases of jaundice the history of a sudden onset with pain could not be relied on. He quoted a case in which a diagnosis of gall-stone having been made chiefly for this reason, operation revealed a scirrhus tumour at the end of the duct. A second case with similar history proved to be one of hepatic hydatid, in which secondary cysts were periodically passed by the gall duct.—Mr. THORNTON, in reply, deprecated the use of the sharp probe as an instrument of diagnosis.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on Friday, Nov. 4th, Mr. C. B. Keetley, President, in the chair.

Mr. PERCY DUNN exhibited (1) the Sac of a Hæmatocele removed during life; (2) an Epithelial Growth from the tongue; and (3) a Kidney with Calculi.

Dr. HERRINGHAM showed (1) a case of Optic Neuritis with preservation of vision; (2) a case of Syphilitic Laryngitis; and (3) one of old Facial Paralysis.

Dr. SPICER read a paper on Obstruction of the Nose, its bearing on Throat and Ear Disease, and its Treatment. The author referred to the scanty amount of literature and observations regarding the functions of the nose in respiration. Dr. Aschenbrandt's observations on the connexion of the nasal functions with aural affections were alluded to, and the fact pointed out that the higher animals normally breathe through the nose, and not by the mouth. Sir Morell Mackenzie has shown the great power of the nasal passage in heating the air, and Aschenbrandt has proved that almost the whole of the warming and moistening of the inspired air takes place in the nose. Constant inspiration through the nose is injurious, and in cases of nasal obstruction the current of air only passing along the lower meatus may cause dryness and catarrhal changes &c. in the pharynx, alteration in the voice, snoring, noisy breathing, sneezing, tickling cough, secondary catarrh, loss of smell, &c. Nasal obstruction may also give rise to exhaustion and collapse of the Eustachian tubes, the rhinitis extending into the tubes, while catarrh and many other sequelæ may result in the aural apparatus. With regard to treatment, the use of cocaine for congestive obstruction was recommended, as well as tubes in place of bougies; also, in suitable cases, the local application of chromic acid to produce bands of contracting cicatricial tissue, and sometimes the galvano-cautery. The removal of polypi and bony growths, and the treatment by fracture of deviations of the septum, were discussed, and the advantages of the saw or nasal trephine, worked by a "dental engine," pointed out. The author concluded by referring to Dr. Curtis's recent observations.—The PRESIDENT remarked on the beneficial use of hazeline in congestive obstruction, as well as of hot water and a cold foot bath. He thought that it was not generally known that a deviated nasal septum is a common cause of nasal obstruction, and that the enlargement of one meatus does not usually compensate for the narrowing of the other.—Mr. SHIELD observed that in an extensive experience in the removal of vegetative growths from the pharynx in children, he had found difficulty with the forceps, and also with the artificial finger-nail; he now prefers the use of his own finger-nail, allowed to grow long for the purpose, followed by the application of sulphate of copper. He requested information as to Dr. Spicer's method of operating in these cases.—Mr. LYNCH related the case of a lady with a dry and hypertrophied tongue, which she had been recommended to have removed; it was, however, discovered in time that nasal obstruction existed on both sides, and that this was no doubt the cause of the changes in the mucous membrane of the mouth.—Dr. THUDICHUM referred to his own experience of over 3000 cases, and stated that, having carefully scrutinised the American results, he had no hesitation in warning the Society against their acceptance. His own radical operations were undertaken solely to remove the disease itself. He regretted that Dr. Spicer had taken no notice of the work done in this country, much of which had been laid before this Society. He emphatically spoke against the use of chromic acid, Sir Andrew Clark's method, operations on the septum, &c., for the cure of reflex neuroses.—Dr. BALL considered that there are certain cases in which escharotics are advisable. Where there is deviation of the septum and narrow meatus, leading to blocking, the galvano-cautery with the help of cocaine is very satisfactory. Cocaine only reduces the swelling temporarily, and there may be subsequent congestion.—Dr. SPICER, in reply, regretted that much of his paper, from its length, had to be left unread, and particularly that part which referred to British work. In answer to Mr. Shield, he stated that he used the forceps as modified by Woakes; the finger cannot remove such growths in adults. The galvano-cautery is, in his opinion, less delicate than the revolving drill. Chromic acid, when used, must be applied with great care to the exact part which is to be cicatrised; if properly employed, no ill results ensue, except perhaps a little catarrh. He considered it unjustifiable to operate simply to remove a growth which had no deleterious effects. He insisted again on the great use of cocaine in certain cases.

Dr. THUDICHUM read a paper on the Varieties of Aconitine, and the Dangers of their Medical Use. The author remarked how often drugs possessing healing properties have powers going far beyond. On account of progressive concentration alarming effects may be produced and a medicine become discredited. The different varieties of aconitine, are due to its varying sources and differences in soil and climate. One variety is actually 4000 times more poisonous than another. Even the so-called "English" aconitine is not always the same substance; one manufacturer may prepare it from A. napellus, another from A. ferox. The German aconitines are also of different strengths, and the French "aconitine crystallisée" is really a nitrate. With such variations, it is surprising that fatal mistakes have not more often ensued. The author has compared the chemical properties of a large number of specimens of aconitine; there are certainly three distinct substances known by the name, and very likely a fourth. They vary in their chemical reactions, as well as in their poisonous power. On account of the danger of their use, he agrees with Professor Gluch that they should all be removed from the Pharmacopœia. He considers that with aconitine paralysis of the sensory nerves is very slight and superficial, and that the motor nerves are more affected. He alluded to numerous experiments on rabbits, and especially remarked on the rapidity of the poisonous effects. In his opinion, the best treatment after a poisonous dose is the swallowing of charcoal and an emetic of sulphate of zinc.—Dr. POPE related the deleterious effects of five drops of tincture of aconite, and stated that since this experience he had given up the use of aconite.—

Digitized by Google

Dr. HERRINGHAM considered aconite a real sedative, relieving pain which resisted all other drugs. As a medicine it was largely used, and not with bad results.—Dr. OWLES corroborated the last speaker, having employed it extensively, and never with evil effect.—Dr. ALDERSON had prescribed the tincture of aconite largely, and had found it most useful in numerous cases. He considered the purity and uniformity of drugs a matter of the utmost importance.—Dr. DODSWORTH thought that the effects of such remedies should be carefully watched; small doses of aconite in his hands had apparently done good.—Dr. WARNER related a similar case to Dr. Pope's. The patient was nearly poisoned by a dose of aconite administered by a homœopathic practitioner.—Dr. THUDICHUM shortly replied.

ULSTER MEDICAL SOCIETY.

THE opening meeting of the session (1887-88) was held in the rooms of the Society, the Museum, College-square North, on Wednesday evening, the 9th inst., at 8 o'clock. There was a large attendance of members.

A vote of thanks having been moved and passed unanimously to the out-going President (Dr. Whitla) for his untiring zeal during the past year, the President (Dr. Esler) delivered his opening address, in which he dealt with the origin and progress of medical matters in Belfast, and compared the practice of medicine and surgery in 1837 with that in 1887. At the conclusion of a very able address a hearty vote of thanks to the President was moved by Dr. J. W. Browne, seconded by Dr. A McConnell, and carried by acclamation. A large number of medical men were nominated for membership.

The following is a list of the office-bearers for this session:—President: Dr. Esler. Vice-Presidents: Drs. Dempsey and O'Neill. Librarian: Dr. H. S. Smith. Pathological Secretary: Professor Sinclair, M.D. Treasurer: Dr. Coates. Secretary: Dr. John McCaw. Council: Professor Dill, Drs. Burden, Kevin, Culwell, O'Connell, and Bigger.

Notices of Books.

Traité Complet de l'Examen Médical dans les Assurances sur la Vie. Paris: J. B. Baillière et Fils. Pp. 571.—An anonymous scientific work must possess strong intrinsic merit before it can command acceptance at the hands of those who are in the habit of gauging every written statement by the known personal equation of the author; it must deal solely with recognised facts or theories, and it must not endeavour to introduce any innovations whatever; in fact, it can only be a *résumé* or rearrangement of common property for the sake of presenting it in an unfamiliar aspect to those who have not leisure to think for themselves. The reader naturally desires to know the status of his instructor, and when this knowledge is denied him, he is tempted either to throw the book aside as unworthy of consideration, or to undertake its perusal in a cavilling spirit, anxious to find flaws which shall justify and explain the author's wish to remain unknown. We are informed that the work above named has been compiled by the physician of one of the French insurance companies, with the assistance of an experienced actuary. Credit is claimed for anonymity on the score of the truthfulness and independence inseparable from a work against which no idea of business speculation may be urged. The scope is ambitious, aiming at filling a supposed gap in medical literature by supplying information of the expectancy of every case, measured by a consideration of the actual physical condition of the life proposed, together with the circumstances tending to curtail this expectancy from the influence of heredity or from the occurrence of previous illnesses. The book is divided accordingly into five sections. An introduction deals with the position of the medical examiner, and his duties to the office employing him, as well as to the individual examined. Then follows a very valuable section upon heredity divided into sub-sections for various diseases. The third portion looks to the previous personal history of the proposer; the fourth describes the precautions necessary in examining the individual; and lastly, in an appendix we find grouped together the medical forms of some few foreign insurance offices, selected for reasons which are not obvious, some notes on the average duration of life, some tables of mortality, and charts in which their value may be easily traced. The introduction is somewhat chatty and discursive, but defends sensibly enough the lengthy medical forms occasionally put before the examiner, amusing examples of temporary mental aberration being quoted. One story seems almost too good to be true: the proposal of a good life was marked "*inadmissible*" by a hospital physician, who was confusing the proposer with a sick person seeking admission to the wards. We are glad to note that heredity is regarded in two directions, ascending and descending, the former of course dealing with the parents, brothers, and sisters, the latter with the children. Descending heredity is very commonly overlooked, but occasions are by no means rare in which inquiries in this direction have been serviceable in dealing with a doubtful case. In this section, however, we meet with a surprise. According to the statements made here, and also later on in the book, the custom of French offices appears to be this: a case is accepted or declined, or acceptance may in certain instances be deferred, but no hint is given of meeting an increased risk by loading the premium; the whole system of extra premiums by which, in this country, certain offices gain largely on insuring unsound lives, seems to be ignored in France. Another point upon which a difference exists is the candour apparently expected from the proposer, for directions are given concerning hæmatemesis, melæna, and other symptoms, for which we have to trust implicitly to the admissions made in our presence. The remarks upon the personal examination of the proposer are, as a rule, sensible enough, but we venture to hope that few members of our profession need so much education when called upon to examine a life; it might surely have been assumed that medical men entrusted with such duties should be able to recognise locomotor ataxy, or to examine the urine for sugar or albumen, without so many detailed instructions. The index and the table of contents appear to be full and useful.

Pathology and Treatment of Ringworm. By GEORGE THIN, M.D. London: J. & A. Churchill. 1887.—The purpose of this work is to describe, so far as is known, the nature and peculiarities of the trichophyton tonsurans fungus, the changes in the human skin to which it gives rise, and the treatment which experience shows is most likely to be successful in destroying the parasite and curing the diseases which it causes. Dr. Thin gives a plain, unvarnished exposition of the subject, conceived in a scientific spirit, and he has successfully kept in view throughout the practical object of the work. There is nothing very new offered to the profession, if we except the results of his cultivation experiments, which lead him to hold that the trichophyton tonsurans is a fungus by itself, and totally distinct from the common fungi whose spores infest all the objects by which we are surrounded, and that the home of this fungus is solely in certain parts of the horny layers of the epidermis of some of the mammalia. Dr. Thin's indications for treatment are clearly given, but such is the diversity of practice that many will no doubt think he has finally adopted very mild and unsatisfactory methods. He gives an interesting and useful account of the plans in vogue in the hands of the Hôpital St. Louis physicians. At the end of the book we find an illustration of the fungus found in some scales from a case of tinea imbricata sent him by Dr. Manson. We miss any discussion of the widespread phases of ringworm, such as

Digitized by Google

are found in many hot climates, and occasionally in this country, and also his experience of the existence of the acute macular form described by Hebra and his disciples.

Anatomy, Descriptive and Topographical. By CARL HEITZMANN, M.D., and LOUIS HEITZMANN, M.D. London: Dulau and Co. 1887.—Messrs. Dulau have published for the English-speaking medical public a translation of Heitzmann's "Anatomischer Atlas," which is so popular a text-book in Germany. The illustrations are very familiar, and in some instances show that the original blocks have been so much worn as to lose in distinctness and finish. The Latin names employed for the identification of the structures depicted will detract materially from its sale in Great Britain, if not in America. We find no special advantage in the work which would entitle us to recommend it to students in preference to the text-books and atlases which are usually recommended in this country.

Anatomy, Descriptive and Surgical.—By HENRY GRAY, F.R.S. Eleventh Edition. Edited by T. PICKERING PICK, Surgeon to, and Lecturer on Surgery at, St. George's Hospital, &c. London: Longmans, Green, and Co. 1887.—Although Mr. Pick has made many alterations in this edition, we are pleased to find that the general character of the book remains the same, and that the peculiar advantages of readability, clear diagrams, and precision of statement have been carefully preserved. The corrections in the work are mainly of errors of detail, which had passed on from edition to edition, but which would necessarily be removed when the work came under the revision of a thorough anatomist and teacher with the reputation of Mr. Pick. In the illustrations to this edition the nerves are coloured, as well as the arteries and veins, but the engravings do not equal in artistic merit many continental works, such as those of Henle and others. A few new drawings are introduced, and one or two which disfigured the preceding edition have been removed.

Manual for the Physiological Laboratory. By VINCENT D. HARRIS, M.D. Lond., F.R.C.P., Demonstrator of Physiology at St. Bartholomew's Hospital, &c.; and D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., Curator of the Museum, and late Assistant Demonstrator of Physiology at St. Bartholomew's Hospital, &c. Fourth Edition. London: Baillière, Tindall, and Cox. 1888.—This work is the outcome of the experience of the authors as teachers of practical physiology in our largest metropolitan school, and is a valuable text-book for histology, practical physiology, and physiological chemistry. The new edition is a great improvement on former ones, especially in the histological and chemical sections.

Pocket Chart for Bedside Case-taking.—Mr. Robert Simpson, L.R.C.P., L.R.C.S., has done good service to his brother practitioners in supplying them with a convenient and handy means of recording notes of cases seen in daily practice. Upon a small thin sheet of paper he has introduced a temperature chart (for four weeks), chest outlines, and columns for the record of the leading features of the case and its treatment. A specimen copy, fully filled in, of a case of typhus complicated with pneumonia, explains the method to be adopted; upon which our only comment need be that the reporter will have to study brevity in his notes. The sheets are contained in a suitable pocket-case, and a record book is supplied for the insertion of each sheet as filled in, an index being appended. The chart is published by Messrs. J. Wright and Co., Bristol.

Letts's Medical Ledger. London: Cassell and Co.—This book has been prepared to be used in connexion with Letts's Medical Diary, and is calculated to make very plain and simple all the bookkeeping required by the profession.

Diaries.—We have received copies of several of Messrs. Letts's Diaries for 1888. These productions are fully equal to those issued by this firm in previous years, their continuous Diaries being especially useful to members of the medical profession.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the Royal College of Physicians was held on Monday, the 21st inst., Sir E. Sieveking, Vice-President, in the chair. The meeting was held in order to affix the College seal to the petition to the Privy Council, and was thinly attended. Before this formality was gone through Dr. Pye-Smith made a few remarks, in the course of which he pointed out that the powers sought by the Royal Colleges to grant degrees in medicine would scarcely satisfy the general desire of the profession for the title of "Dr." to be conferred on all qualified practitioners, and that the formation of a Medical Faculty only would not advance the cause of education to the required extent, which could only be accomplished by a combination of teaching and examining bodies in London, including the University of London. He believed the time would come when such a combination would be effected.

The Moxon Memorial Committee having expressed their intention of devoting the surplus of the fund (after defraying the cost of the erection of a memorial tablet in Guy's Hospital) to the foundation of a gold medal for clinical research to be awarded on the recommendation of the President and Council of the College every three years, it was resolved on the motion of Dr. Pavy, seconded by Dr. Handfield Jones, that the offer of the committee be accepted.

The Treasurer gave notice of his intention to propose the following resolution at the next meeting of the College: "That, in recognition of the protection afforded to this College by the police during the recent riotous proceedings in Trafalgar-square, and of the admirable discipline exhibited by that force under prolonged provocation, the College do vote the sum of twenty-five guineas as a contribution towards the funds of the Metropolitan Police Convalescent Home, or towards any project approved by the Chief Commissioner of Police."

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.

AT a meeting held at the Medical Society's rooms on Nov. 22nd, Dr. B. W. Richardson delivered an address, in which he replied to the recent statements of Sir W. Roberts in favour of alcohol. He pointed out that the one nation which had exhibited the most marvellous vitality for centuries—namely, the Jews—was distinguished for its sobriety. The Turks also, but for bad government, would be amongst the foremost; while, on the other hand, Spain, in which there was not a single temperance society, perhaps hardly an abstainer, had degenerated from its position as the leading nation of Europe. Centuries ago the conquering bands of Mahomet had carried all before them, and in the other waves of invasion which had passed over the world it was the more sober which had proved victorious. As to the death-rate, that of Norway and Sweden had markedly improved since the reform of the licensing laws a quarter of a century ago. Our own death-rate had diminished concurrently with the spread of total abstinence, though of course not entirely due to that cause. Russia had the highest death-rate of any European country, and consumed enormous quantities of alcohol. He also referred to Dr. Murray's lecture against regular habits as a revival of the exploded Brunonian theory, and said that such advice to men and women reclaimed from intemperance would be most disastrous.

A paper was also read by Dr. J. J. Ridge on "Alcohol—its Substitutes and Alternatives," in which he urged the desirability of not recommending alcohol if any other drug or measure would suffice, and expressed the opinion that if this were conscientiously followed out the profession would administer alcohol in ever-decreasing quantity. It was stated that the Association is the largest association of medical men, save one, in the United Kingdom, numbering 350 members and 75 associates (students); also that the news had been received of the total abolition of the ration in the British Army in India.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 26, 1887.

ALTHOUGH the subjects which the General Medical Council have under consideration during the present session are not calculated to command the same interest as those which related to the maintenance of the Societies of Apothecaries as licensing bodies, they none the less require considerable judgment and skill in their adjudication. The Council is, however, well constituted to perform its duties. The fact that it is presided over by Mr. JOHN MARSHALL is alone a guarantee that it will have due regard for the honour of the profession, and that every effort will be made to ensure that its labours will bear fruit; while the recent addition to its numbers of Sir GEORGE MACLEOD and of Dr. SAMUEL WILKS will give it fresh strength. The accession of Dr. WILKS at a moment when efforts are being made to increase the thoroughness of medical education is an event upon which the profession are to be congratulated.

The address of the President placed tersely before the Council the nature of the subjects which must engage their attention. Of these, perhaps the most important is the employment of unqualified assistants. The placing of patients under the sole charge of unqualified persons is we are told, becoming more largely condemned by the "representatives of the public sense of justice," and recent judicial decisions have rendered it impossible for claims to be enforced for payment for services of this character. This is so far satisfactory, but it is a tedious method of preventing a custom which all right-minded persons must disapprove. The committee to whom this subject was referred embodied in their report that it was worthy the attention of the Council that one excuse for the employment of unqualified assistants was the want of knowledge sometimes possessed by young qualified practitioners. Serious objection was taken to the incorporation in the report of this last paragraph, and eventually it was not adopted. The two subjects are not, indeed, related, and the decision we hold to be a proper one. If medical education is faulty it must be amended, but we cannot allow that any insufficiency in this respect need be entertained as affecting the employment of persons who have not submitted to the tests which the law requires in the interest of the public. Dr. WILKS undoubtedly showed much reason why the practical element in medical education should receive more serious attention. It is a standing reflection on the present system that many men pass through the schools without becoming conversant with maladies so common as measles and scarlet fever. Opportunities exist where maladies of this sort can be studied in public institutions, and it is the fault of the teachers if students can leave their schools without having made themselves acquainted with them. Perhaps the greatest reflection upon the teaching of the present time is the neglect to thoroughly study vaccination. Apart from the few visits which may be paid to a public vaccination station the operation is not thought of, and there is, we believe, hardly a reference made to the subject in a single lecture on medicine delivered during any session.

The Council have further engaged themselves with the question of registration of foreign degrees. Already more than two hundred applicants have sent in their claims for their degrees to be registered, and the committee to whom the subject has been referred have recommended that the Registrar be authorised to register the degrees from universities where examinations had been properly held. The report of this committee was postponed for further consideration.

The Society of Apothecaries have not shown themselves wanting in a desire to maintain the position of their body as an active participator in the granting of diplomas. They have now come before the Council with a request to grant a registrable diploma in Public Health, and have submitted a programme which, if faithfully adhered to, will enable them to take a prominent position in advancing the study of this subject. Compliance with their request has been postponed for the purpose of obtaining a legal opinion on the meaning of the Medical Act in this particular, but there is little doubt they will shortly be in the enjoyment of the right they desire.

The President has given to the Council an opportunity of performing a useful work in taking steps for the simplification of the methods of dealing with cases arising under the penal clauses of the Medical and Dentists Acts. There is much to be said for leaving to the various licensing bodies the duty of taking the first step for the removal of a name from the Register by the withdrawal of their licences in cases of infamous conduct in a professional respect. But the need for equality of procedure is evident, and the Council will have to overcome this difficulty before they can hesitate to take the initiative in proceedings necessary for the vindication of the honour of the profession.

The rearrangement of the work of the General Medical Council promises to make its labours more productive than heretofore. The Council have this session been summoned, as the President announced, for the discussion and settlement of certain specified subjects, particularly for the consideration of questions connected with the completion and rectification of the Registers. In the spring the Council will meet especially for the consideration of matters relating to education and examinations. By this arrangement the waste of time which formerly characterised its meetings, and which was frequently condemned in these columns, will be prevented. The experience Mr. MARSHALL has had as chairman of important committees has enabled him to decide on the manner in which the Council can most economically employ its time; and the system now adopted is well calculated to attain the end that is desired. If the Council should succeed, as they hope, in relieving themselves of the prolonged investigation into matters relating to "infamous conduct," they would be much more free to devote themselves to the many other important subjects which require settlement.

The placing of a marble bust of Sir GEORGE PAGET in the Council Chamber is a fitting tribute to this distinguished physician. As President of the Council, Sir GEORGE PAGET

Digitized by Google

had rendered services which well deserved to be remembered by those who had served with him.

AT the present time several circumstances combine to centre both professional and public attention upon those malignant diseases grouped under the heading of Cancer. Renewed efforts are being made to elucidate the nature of the disease, and the question of its contagiousness has been the subject of many letters recently published in our columns; and while the surgical treatment of cancer was never prosecuted with more zeal or a greater measure of success, the hope that some drug may be found which will have the power of arresting these malignant growths must receive a fresh impetus from the remarkable cases published by Prof. CLAY in our last week's issue. But more than all, the illness of the Crown Prince of Germany, which illustrates most of the salient points in the clinical history of cancer, is an object-lesson which the whole of Europe cannot fail to read. It illustrates the proneness of the disease to attack the robust and strong, its insidious onset, its stealthy progress, the enormous importance of a correct diagnosis in the early stages of the malady, the extreme gravity of the issues at stake in its proper treatment, and the unerring certainty of its result unless successfully dealt with in its earliest stage. All these are points long familiar to the profession and only too well known to many individuals among the public, but never before have they been demonstrated with such tragic effect as now. It is impossible to write of the Crown Prince's case, even in a medical journal, without a word of tribute to his heroic courage, often before tested in the fierce scenes of war, but never more nobly shown than in the calm and manly way in which he is facing a more relentless foe than can be encountered on the battle-field. When commenting on this case in the summer we could only write with reserve, for the uncertainty that prevailed, and the desire to entertain hope so long as it was at all possible, prevented a more emphatic criticism. Now, however, all doubt as to the nature of the affection has been removed, and we are in a position to speak more freely. Upon certain personal issues that have been raised in some quarters we do not intend to enter, for they are out of place in the presence of so far-reaching a calamity as that with which we are dealing. But we ought to refer to one view in which this matter has been presented for the sake of protesting against it. An attempt has been made to exalt Sir MORELL MACKENZIE'S intervention in the case into a national incident. Nothing is more incorrect. Surgery is too cosmopolitan to warrant such a conclusion under any circumstances, and Sir MORELL MACKENZIE was not called in to attend the Crown Prince in any way as a representative of British surgery. It was a purely personal matter; his opinion was sought on account of his great reputation as a laryngologist, his extended experience, and his acknowledged dexterity in all intra-laryngeal manipulations.

There is a danger lest the course of the Crown Prince's case should bring undeserved discredit upon intra-laryngeal surgery, and upon the value of the microscope in diagnosis. It is important to lay stress upon the fact that there is no evidence to lead to the opinion that the nature of the Crown Prince's disease has undergone any essential change. It is not as if some very chronic affection had suddenly assumed an active character. The rapid and continuous development of the case shows that it was cancer in the spring, and cancerous ever since its activity has been noticed. Were this not insisted upon, the case might be used as an illustration of the mischievous effects of intra-laryngeal operations in converting benign growths into malignant. The case also shows once again that the value of the microscope in diagnosis is of positive rather than of negative value. It can throw light upon the structure of what is submitted to it, but it cannot go further. The examination of a minute fragment of a growth may prove it beyond doubt to be cancerous, but, on the other hand, if it shows the absence of any distinctly cancerous elements in the part examined, this cannot be implied to hold equally true of other parts of the growth. When employed for clinical diagnosis the microscope may prove the presence of cancer, but it is alone insufficient to prove its absence. It is to be regretted that this fact was not sufficiently insisted upon by the distinguished pathologist to whom the portions of growth removed by Sir MORELL MACKENZIE were submitted. For while the profession fully realised that his reports were insufficient to rest a diagnosis upon, the laity were naturally led to attach greater weight to them.

The treatment of laryngeal cancer may be classed as either palliative or quasi-curative. The palliative treatment waits on symptoms, and its chief value lies in the performance of tracheotomy to provide a free passage of air to the lungs. It is this course which the Crown Prince has decided to follow, and we trust that it may be long before any active interference is called for in his case. The curative or quasi-curative treatment aims at entirely eradicating the disease at an early period, in the hope of permanently arresting the disease or of obtaining a long immunity from it. Its success depends upon the thoroughness with which not only the obvious morbid products, but a considerable area of apparently healthy tissue around them, can be excised. When once a cancer has developed, every week such an operation is postponed both adds to its gravity and lessens its prospect of utility. Moreover, the operation, even when reduced to its simplest proportions, is a very grave one, attended with considerable danger to life and with serious impairment of the voice. It is right to run these dangers when the prospect of success is good, but as the progress of the disease both adds to the dangers and lessens the prospect of success, the time soon comes when the balance is turned and the operation is no longer admissible.

WE are reluctantly, but unavoidably, compelled to emphasise the arguments adduced in our last two issues against the inauguration of a systematic attempt to popularise the science and art of medicine; and still more unwilling are we obliged to recognise the need of giving very forcible expression to those views which we have already briefly laid before our readers as to the mistaken and mischievous policy of the members of our profession who have committed themselves to this extraordinary enterprise. It would seem unnecessary to contend, at greater length than we have already argued,

Digitized by Google

that the distinction between popularising the laws of health—which is not only possible, but highly expedient—and endeavouring or pretending to popularise the laws and practice of medicine—a task which every tyro in science well knows to be impracticable—is self-evident. If the knowledge of disease were a formulated and demonstrable science, and medicine a complementary applied science or art, so that each set of symptoms indicated the exhibition of a particular drug or method of treatment, anyone who either possessed a Concordance of Symptoms and Remedies for ready reference, or who could commit such classified lore to memory, might set up practice as a physician or undertake the duty of domestic management "in disease." But, as everyone who has only a superficial acquaintance with the subject is aware, the knowledge of disease, or of diseases, is not a formulated or demonstrable science, and still less have particular symptoms their cognisable remedies. So far from either of the above premisses being admissible, precisely the same symptoms, even similarly associated in groups, may be produced by totally different causes and bespeak diametrically opposite states of ill-health requiring absolutely antagonistic agents and modes of treatment; while, as regards the exhibition of particular drugs for particular symptoms, the choice between acid and alkali, between stimulant and depressant, between aperient and carminative, may make all the difference between life and death. To give only one illustration of this position which at the moment occurs to us: The diagnosis between some forms of colic and a sudden attack of peritonitis secondary to perforation of a gastric ulcer is one which may be extremely difficult for even a skilled practitioner to make, and the use of an even moderately powerful aperient which might be highly helpful in the one case would perhaps cause death within a few hours in the other. How is it possible to place the unskilled in a position to act with safety in an emergency like this? Yet such an illness is precisely the sort of emergency in which, with the temerity engendered by "a little knowledge," the practitioner of a popularised medicine would be sure to act. There is a popular belief that a special cherub sitting up aloft watches over poor Jack when he is drunk, and that the same or an equally benevolent providence protects children. We do not remember to have heard of any particular cherub told off to guide the wits of amateur practitioners of popularised medicine, albeit there will be sore need for the special intervention of such help if the poor children who are to be "managed in health and in disease' under the patronage and direction of the new propaganda are not saved from the peril that besets them by the honourable withdrawal of those members of our profession who have lent their names to the undertaking, and a candid avowal on their parts, either in our own columns or through some suitable medium, that they have been misled.

All endeavours to inspire the public with medical knowledge and power are false, and must fail. It is opposed to the spirit and tendency of modern enlightenment to entertain or encourage the belief that work so *difficult* and *dangerous* as the treatment of the sick can be done without knowledge and skill, the result of long and arduous study and training. It is startling to find that really thoughtful and well-informed men are connecting themselves with such a policy at the very moment when they are strenuously insisting on the need of technical education, and attributing the deficiencies of British industry to the lack of such training! If it be desirable that working men should be specially instructed because they cannot do the ordinary and simple work of their crafts without special training, how comes it to pass that sagacious and competent authorities are practically encouraging the public to believe that a few vague hints thrown together in a popular periodical can qualify them to deal with the incarnate mystery of organic animal life *in disease?* Do the propagators of this perilous heresy realise their grave responsibility? Has it occurred to them to estimate the magnitude of the mischief which may ensue if, in some case of serious but unidentified disease, not only is precious time wasted, but possibly a destructive method of treatment adopted by some person acting on the hints they cast broadly before the public without having the least control over the application which will be made of their suggestions? It is no answer to this appeal that the drugs prescribed are very simple, and the directions given exceedingly plain. How easy, even in plain cases, is it to blunder so that life may be allowed to slip away or death be actually induced? We protest against the procedure as an outrage on common sense, and as opposed to the whole principle of medical science and practice.

We have no sort of interest in thus writing. Those critics who twit us with advocating what is decried as a "professional" view of the question are very much at fault even as the matter lies from their own standpoint. Nothing could by any possibility tend more directly to "make work for the doctors" than that the unskilled should take to physicking themselves. Every man his own lawyer is a mine of wealth to the legal profession; every man his own physician and physician to his own family would speedily issue in an overwhelming demand for the services of skilled practitioners of medicine to repair the grave injuries inflicted by those who know neither the work nor the tools. It is on far higher ground than that of selfish interest we take our stand in discussing this question, and the only consideration of a professional nature that has weight with us is that which relates to the discredit and humiliation thrust on the profession by the fact that some of its best known and most trusted members stand committed to the task of attempting that which we and they both *know* to be impracticable in its completeness, and full of the gravest peril in its insufficiency. Unless the public can be placed on precisely the same footing of knowledge and competency with the professors of medicine, they cannot safely undertake their work—a work which to the most erudite and skilful amongst us is one of great responsibility and difficulty; and if it be possible to give the public even a *safe* minimum of knowledge by popular discourses about management in disease, then, of course, it is possible to make medicine an accessory branch of ordinary education, and the sooner it ceases to be regarded as the business of a profession the better.

DURING the autumn of this year there has been, and still is, considerably more scarlet fever in London than has been usual for the last few years. It is a matter for doubt,

Digitized by Google

however, whether there is sufficient to be dignified by the name of an epidemic, or whether the public would be aware of its existence were it not for the punctual appearance of the statistics of the Metropolitan Asylums Board in every morning paper.

During the months of August, September, and October somewhat less than 3000 patients, drawn from a population of 4,000,000, have been admitted into the hospitals of the Board, and it is probable that these contain at least one out of every five of the recognised scarlet fever cases now in London. If this estimate be not excessive, it would show that there have been during this autumn at most fifteen cases to every 4000 of the population. Now, at the last census it was seen that the increase of the population during the ten preceding years amounted to 14·36 per cent.; in other words, there were among every 1000 people 143 under the age of ten, or among 4000 people 572. It is probable that at least one child in every four has recognised scarlet fever under the age of ten; so that if fifty-seven children be born yearly in a population of 4000, we may expect that there will be on an average at least sixteen scarlet fever cases every autumn; whereas there are, as has been shown, probably not more than fifteen at present. These figures may be taken as approximately correct, and they show that, far from there being an epidemic of scarlet fever, there is at present less than may be expected in future. On referring to the reports of the Asylums Board it may be seen that the numbers yearly admitted into its hospitals show a gradual but steady increase, and also that while the numbers are increasing the death percentage is slowly diminishing; and, further, it may be seen from the report of the Registrar-General that the proportion of deaths from scarlet fever which occur in these hospitals is increasing, and has already reached nearly 40 per cent. In other words, these hospitals, originally intended for pauper patients, have inspired so much confidence, that practitioners and parents are sending their infected sick to them in such numbers as to give rise to the idea that there is at present a serious epidemic of fever "raging" in London. It is probable that in its clinical aspect the scarlet fever of this autumn does not differ greatly from that of any other autumn. The mortality may be taken to be 7 per cent., which is satisfactory, and it is probable that this average could be very much reduced if the poorer children were removed sooner from their dirty and unhealthy homes. Among eighty-three deaths at two of our largest hospitals, twenty-four occurred within two days of the patients' admission. In other words, these hopeless cases, most of them with sloughy throats, swollen neck, discharging nostrils, and much asthenia, were only kept alive for forty-eight hours by the free use of alcohol. Some form of kidney mischief is responsible for 12 per cent. of the deaths, but of course, if the so-called cases of "scarlatina maligna" which have been already mentioned were eliminated, this number would be greatly increased. It is exceedingly difficult to give statistics as to the vague term "albuminuria," for albumen in traces may at some time be nearly always found, but it may be said that it occurs in appreciable quantity and for a considerable time in from 15 to 20 per cent. of the cases, and among these it occurs mainly in those patients who are anæmic and have been formerly badly clothed and ill-nourished, and it frequently occurs in two or more members of the same family. As it is difficult to define albuminuria, so is it to say what is and what is not acute nephritis, but it will be found that from 5 to 7 per cent. of the cases have either high temperature, vomiting, hæmaturia, or dropsy, together with albuminuria, and of these a very considerable proportion are admitted already desquamating. Among these desquamating cases, such a large number are the subjects of renal disease that it would be interesting to know whether they are suffering from the neglect of due precaution, or whether they represent the 7 out of 100 cases of unrecognised scarlet fever daily spreading the disease. Convulsions have not been common in the nephritis of scarlet fever, and are not serious. Lung affections have occurred, either as complicating the nephritis or alone, in 16 out of 113 fatal cases, pneumonia being the more common form, and pleurisy rare. No case of empyema has been noted. In about 8 per cent. of cases acute laryngitis has been the cause of death, and in two of these membrane has been noted. It has occurred that a patient suffering from scarlet fever has lost a brother on whom tracheotomy was performed at a general hospital for what was diagnosed to be diphtheria. Scarlatinal rheumatism is another vague term, and one which does not lend itself to statistics. During this autumn a larger number of the patients than is usual have been adults, and of these about the ordinary proportion have had pains in the joints without any sign of endocarditis or pericarditis. Joint affections in the younger patients have, as is customary, been of rarer occurrence, but more serious in their nature. Throat complications have, perhaps, been rather more common than is usual, sloughing tonsils, cellulitis of the neck, and sloughing of the cervical tissues having occurred in about 12 per cent. of the fatal cases. As regards the duration of the disease during the present autumn, it will probably be found that accordingly as the fever is of a milder type, so will its duration be lessened; but it may be safely said that the average will not be under fifty-five days. It is customary to isolate the patient until the desquamation is entirely completed and there is no roughness of the heels or ankles. It is a popular belief that this will always have occurred by the end of the sixth week. The annexed table, taken from a memorandum made for another purpose, will, however, show the true facts of the case:—

Duration of Scarlet Fever.

Oct. 1st to Sept. 30th.	Cases.	Days.	Average.
1877–78	305	20·542	67·31
1878–79	376	26·666	70·92
1879–80	704	39·242	55·74
1880–81	413	30·727	74·39
1881–82	497	35·117	70·65

DR. PEKELHARING of Batavia, who, as has been mentioned (see THE LANCET, Sept. 24th. 1887), recently discovered and cultivated the micrococcus of beri-beri, is to be granted a considerable sum by the Dutch Government to maintain his bacteriological laboratory at Weltevreden, near Batavia, so that his important investigations may be continued.

Annotations.

"Ne quid nimis."

METROPOLITAN HOSPITAL SUNDAY FUND.

THE Right Honourable P. de Keyser, Lord Mayor, president and treasurer of this fund, has requested the attendance of the members of the Council at a meeting at the Mansion House on Monday next, the 28th inst., at 3 o'clock. The business of the meeting is to determine the report of the Council for the year 1887, and to order its publication; to revise the list of the Council for 1888; to order the convening of the next annual general meeting of constituents on Monday, Dec. 12th, at 3 o'clock; to consider what day of 1888 shall be recommended to the constituents for the sixteenth Hospital Sunday; and to transact general business. Again this never-ending and anxious work, the support of our large hospital system in this vast metropolis, is commencing to engross the attention of the members of the Council of the Fund. We earnestly hope that a large number of the Council will respond to the call of the Lord Mayor, who will take the chair for the first time as president of the Metropolitan Hospital Fund, although he has long been known as an active member of the Council. The Sunday Collection for 1888 must not be allowed to exhibit a falling off in comparison with the results of former years; on the contrary, it must be a yet further advance on the amount collected during the last two Hospital Sundays. Supposing it to be again ordered by the Council that a "Hospital Week" shall be arranged as in the last two years, in accordance with the suggestions of Dr. Wakley, the late Editor of this Journal, we propose to publish two or three detached Supplements, which, in addition to a reprint of all leading, special, and other articles on the Fund that may appear in the pages of THE LANCET between the present time and the date fixed for the collection in 1888, will contain shorthand reports of the speeches of the different noblemen and gentlemen who will attend these meetings, to advocate the interests of the London hospitals with reference to the coming Hospital Sunday collection. These Supplements will, as on a previous similar occasion, be distributed gratuitously to the clergy, staffs and governing authorities of the various metropolitan hospitals, and to all who are already interested, or who may be moved to interest themselves, in the prosperity of our metropolitan medical charities.

PROFESSOR KREMIANSKI'S ANILINE TREATMENT OF PHTHISIS.

PROFESSOR KREMIANSKI, who, it may be remembered (see THE LANCET, March 5th, 1887), proposed, at the Moscow Congress of Russian medical practitioners held at the beginning of the present year, to treat phthisis by means of aniline, and whose views were generally condemned at the time, has just published a long letter complaining bitterly that he has been misrepresented and misunderstood, and that the most influential medical journals in Russia have refused to admit papers by various observers which contained favourable reports of trials made of the treatment, while prominence has been persistently given to all unfavourable and unsuccessful cases. Again, it seems that the bactericide treatment by no means consists merely of aniline inhalations, but that many other substances are employed either in conjunction with aniline or without it. The detailed description of the treatment is set forth in Professor Kremianski's book, and apparently has not been at all accurately reported in any of the better known Russian journals. He is anxious to point out that some observations which have recently been published on the action of aniline in large doses on the lower animals do not really militate against his views, because he never proposed that more than very minute doses of aniline should be given. He is quite prepared to admit that his plan of treatment is as yet very imperfect, and that it requires much more elaboration; but he insists that his later experience only goes to confirm his belief in its value, and numbers of brother practitioners who have tried it fairly have obtained good results. He expresses his regret that he has as yet been unable to make arrangements for publishing his book in some language more accessible than Russian to the majority of foreign medical men, from many of whom he has, he says, received inquiries about his system.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN (SCOTLAND).

MOST of those who are interested in vital statistics must at some time or other have felt more or less inconvenience from the absence of sufficient uniformity in the statistical returns issued by the three Registrars-General for England, Scotland, and Ireland. The weekly, quarterly, and annual reports for England and Ireland do, it is true, very closely correspond in most of the essential particulars, but between the reports issued from Edinburgh and those issued from London and Dublin, the amount of divergence, to say nothing of the dates of issue, is such as to place most serious obstacles in the way of a useful comparison of the vital statistics of Scotland with those of England and Ireland. The Quarterly Return for Scotland recently issued, and relating to the three months ending with September last, presents some of these features of nonconformity. More than fifteen years ago the Registrars-General of England and Wales changed the form of their Quarterly Returns, in order to show the number of deaths registered from each of the principal zymotic diseases, and other details of the deaths, in each registration sub-district. The Scotch Quarterly Return, however, now as then, only gives the numbers of births and of deaths registered, without any clue to the causation of the deaths, thus depriving the return of their most important feature as a measure of sanitary condition. Not content, moreover, with this omission from the general return, a paragraph in the introductory remarks invites the reader to make an erroneous assumption from the statistics of fatal diseases in the eight largest towns which are published in the return. Having stated that about 32 per cent. of the entire population of Scotland resides in those eight towns, the report adds: "it may therefore be assumed that diseases which are prevalent in them will be found to a similar extent in the surrounding districts." We feel bound to protest against the publication of such untrustworthy official assumptions at the public expense. There is, moreover, inconvenience in the custom that prevails in most of the Scotch reports of giving all rates of births, deaths, and marriages to population as percentages in the tables, and to quote them in the remarks as rates to 10,000 persons living, whereas in the English and Irish reports all these rates are quoted to a thousand living. In this protest against nonconformity in the vital statistics of the three parts of the United Kingdom, it is but fair to add that in two important respects the Scotch quarterly is more complete than the English or Irish returns. The Scotch return gives the numbers of marriages recorded in the same three months as are dealt with as regards births and deaths; whereas in the English and Irish returns this information is three months behind date in the quarterly returns. Surely some way should be found for bringing the marriages in the English and Irish returns up to date, as is done in the Scotch return. Again, the Scotch return distinguishes the illegitimate from the legitimate births, which is not done in the English and Irish quarterlies; we doubt, however,

Digitized by Google

whether this information is worth publishing in a quarterly return, as it naturally appears in the annual reports. The report before us shows that during the three months ending with September the birth-rate in Scotland was 30·4 per 1000 against 31·2 in England and Wales; and the death-rate was 16·8 in Scotland, against 17·6 in England. The rate in Scotland ranged from 18·4 in the principal towns (which was 2·0 below the rate in the largest English towns), to 17·3 in other town districts, 14·0 in the mainland rural districts, and 13·4 in the insular rural districts. In consequence of the deficiencies in the Scotch quarterly compared with the English and Irish returns, it is impossible to compare the rate of infant mortality or the causes of death in the several parts of the United Kingdom, or it could probably be shown that the excess of the death-rate in England last quarter, compared with that in Scotland, was mainly due to excess of infant mortality from summer diarrhœa. It is noted in the Scotch quarterly that 8·2 per cent. of the births registered in Scotland during last quarter were illegitimate, the proportion of illegitimacy ranging from 7·1 per cent. in the large towns and insular rural districts, to 10·0 per cent. in the mainland rural districts.

CAUSE AND EFFECT OF EXCESS OF FAT IN HUMAN MILK.

DR. ZALESKI of Dorpat publishes a case in the *Vrach* which bears out the well-known doctrine that a peasant wet-nurse should not be made to change her habits and her food for those customary among persons belonging to the wealthier classes of society. A baby four months old was brought to Dr. Zalêski with a history of diarrhœa and an emaciated appearance. The wet-nurse, a peasant woman, who had been accustomed to live on black bread, potatoes, and very small quantities of milk and cheese, with no alcoholic liquor, was suddenly promoted to a rich and highly nitrogenous diet, consisting of quantities of meat and eggs, with at least two bottles of beer a day. Samples of the milk were analysed. By Dr. Zalêski's advice her diet was changed so as more nearly to resemble that of her peasant home, the beer was stopped, and she was given some light manual labour to perform. At the end of a fortnight a great improvement had taken place. Her milk was again analysed. The mean results in the two cases showed that there was but little difference in most of the constituents. The lactose, however, had increased from 4·40 to 5·46 per cent., and the fat had decreased from 6·29 per cent. (which was the high figure denoting the proportion of fat in the first sample) to 3·97. Dr. Zalêski goes very fully into the literature of the subject, and gives analyses by many other observers. The conclusion to which he comes is that an excessively high percentage of fat in the milk, so far from being beneficial, is actually prejudicial to the health of the child; and that a highly nitrogenous diet tends to produce excess of fat, and, to a smaller extent, an excess in the saccharine matter in the milk.

BREATHING SPACES IN TOWNS.

AMONG the various projects the intention of which is to provide for the physical well-being of our population, there can be none of greater interest or importance than that which is concerned with the purity of our surrounding atmosphere. There are movements on foot for the better distribution of the pressure of work, for the suitable housing of the poor, for the supply and regulation of food in accordance with physiological necessity, and a variety of other useful purposes. None of these, however, can claim a higher title to consideration than the question which has to do with the feeding of the blood by respiration. Upon the efficiency of this process all else in the way of vital function must, of course, depend, and the question accordingly becomes a most pressing one where, as in great cities, breathing air is as far from purity as the simultaneous demands of countless overcrowded human beings and of coal-fed fires can make it. We cannot, in the face of this fact, pretend that the conditions of town life do not affect more or less injuriously the physical state of the inhabitants. Women and children suffer to a large, men to a relatively less, extent; but the fact of impaired health chiefly attributable to this cause is in numerous instances proved by the evidence of diagnostic signs. The tendency of an in-coming rustic population to frequent already congested urban districts cannot soon or easily be restrained. It will apparently continue with practically no limit for an indefinite time, and it behoves us therefore to do our best to provide in towns, and in all parts of them, that ready access to pure air which is so essential. For children especially, as being the embodied promise of coming generations, and as requiring almost more fresh breathing air than adults, it is most desirable to secure this boon. Fortunately, much has been done in this direction already. Among other agencies, the Association formed for the purpose of opening up vacant spaces in the metropolis for public recreation maintains an increasing activity in its useful work. Its labours are from time to time commended to public notice by the voice and pen of its energetic president, and we cannot but add to his utterances the statement of our hearty approval and support alike on grounds of rational theory and practical observation.

THE NORWICH INFECTIOUS HOSPITAL.

THE action of certain authorities with regard to the isolation of infectious diseases is bringing considerable discredit upon our system of health administration. The latest case in point has occurred at Norwich. In 1872 the Corporation acquired, to a large extent by gift, an iron infectious hospital, which now belongs to and is maintained by the town; in short, it is a hospital which, according to the Public Health Act, 1875, has been provided "for the use of the inhabitants." Two cases of scarlet fever having occurred in Norwich, the vicar of St. Peter, Mancroft, endeavours to get them removed to this place, which is professedly kept up by the rates for the prevention of the spread of infection. He is first bandied about from medical officer of health to inspector of nuisances, and thence to a chief clerk; and after on one occasion having wandered about for four hours, all he can do is to enter into an undertaking to be responsible for all payments on behalf of food, light, and firing, and subsequently he is further asked to promise that he will pay a guinea a week for a nurse. Having thus willingly consented to be fined a substantial sum in the interests of the public, he awaits the removal of the patients, but this was never effected; one died and the other has reached a state of convalescence in the place where they were both originally attacked. We are aware of the fact that the Public Health Act says the Town Council may demand payment for maintaining such patients in hospital; but how any sensible authority can prefer getting hold of a few odd guineas to securing the removal of the infectious sick from amongst the population, who have the right to look to them for protection against infection, passes our understanding. They might as well refuse to send the fire engine to put out a fire at a poor man's house until someone undertook to pay them for the hire of the horses and the cost of the water that would be consumed. According to the vicar's statement, the inspector of nuisances told him that poor people were not welcome at the hospital. That is to say, the very class who are most unable to deal efficiently with infection in their houses are the ones whom the authority desire to keep in

Digitized by Google

the midst of the community. It is the obvious duty of a sanitary authority to receive into such hospital as has been provided "for the use of the inhabitants of their district' those inhabitants needing isolation, so long as suitable accommodation exists for them; and if the town is so circumstanced that it needs in its infectious hospital means for classifying patients according to their social status, as well as according to disease, this should be provided. But to refuse cases because there are only twenty-five beds, whereas ninety would be needed if all cases were to be received, is to admit that there has been a failure on the part of the authority to do its duty to the community who elect them to their office. And yet we learn that this is one of the excuses put forth. The Norwich infectious hospital has for a long series of years not been successful as regards the prevention of the infectious fevers of the district; and the inhabitants must themselves determine whether it is so to remain. In connexion with the questions raised in this case we would refer to that of the Leeds Corporation Hospital, mentioned elsewhere.

EXOPHTHALMIC GOITRE.

WE may look to rare morbid associations of ill-understood diseases for some elucidation of their pathology. Considerable hypertrophy of the tonsils has been observed in association with hypertrophy of the thyroid, and such a connexion suggests many ideas which it can do no harm to entertain, but by which we must not set too much store. Sometimes considerable mental disturbance may accompany other symptoms of exophthalmic goitre. The insane state has occasionally been of that description met with frequently in general paralysis—the expansive and grand sort. Why the right lobe of the thyroid and the right-sided proptosis should be greater than the left, supposing the observation to be true, may be dependent on other causes than a sympathetic nervous association. Though ophthalmic goitre is most frequent between the advent of puberty and the full development of womanhood, yet children and aged persons may present all its signs. Benedikt places the essential lesion in the medulla oblongata, Eichorst in the grand sympathetic, and Filehne in the restiform body, whilst Charcot considers it as a general neurosis allied to hysteria, and other authors believe it to be specially related to chlorosis or anæmia.

FEVER IN LONDON.

SCARLET fever was last week rapidly diminishing in London, the numbers admitted during the week ending Nov. 18th being 174, or 54 less than in the preceding week. During the present week there has been some increase in the number of persons attacked with this disease, the epidemic behaving as we ventured to predict that it would, and showing a general decline, with a temporary increase during this month. It will probably not be many days before the cases again diminish, and during December the decline should be strongly marked. We note that in the report of the last meeting of the Metropolitan Asylums Board on Saturday last, it was proposed to make a considerable increase in the hospital accommodation for cases of scarlet fever. We believe that this provision will not be required, and that after the next few days the discharges will so far outnumber the admissions to the hospitals that any overcrowding which at present exists will cease. Of other diseases under treatment in the Managers' hospitals, enteric fever contributed fourteen cases and small-pox seven during last week. The Metropolitan Asylums Board have received from the Local Government Board a letter stating that the Board cannot comply with the Managers' application for authority to remove to their hospitals all persons suffering from fever or small-pox whose removal shall be applied for by duly qualified medical practitioners, as they are of opinion that they are not empowered to issue such an order; but they have reminded the Managers that the medical superintendents are empowered to retain persons presenting themselves for admission whose condition is such that it would be dangerous to refuse them admission. It is unfortunate that the law does not permit a larger discretion to the Local Government Board, for there can be no question as to the desirability of the course the Managers suggested. The Metropolitan Asylums Board have also had under consideration a letter from the Society of Medical Officers of Health, urging them to address a request to the Local Government Board for a Bill to be brought in for the compulsory notification of infectious disease. This step has now been taken by the Managers.

THE MEDICAL WITNESS AND THE JUDGE.

AT the late Nottinghamshire Assizes, before Mr. Baron Huddlestone, John Webster, a collier, was indicted for having caused grievous bodily harm to Frank Holmes, at Worksop, on Aug. 8th. The prisoner was convicted, and sentenced to eighteen months' hard labour. From the reported evidence, it appears that during an altercation between the prisoner and the man Holmes, the latter was kicked, and had both bones of the leg broken just above the ankle. Dr. Hogg, who attended Holmes, testified that in his opinion the leg was broken by a fall, and not directly by the kick. We are inclined to believe that this view of the case is correct, because there was no bruise or abrasion of the skin over the seat of fracture, which we certainly think would have been the case had the alleged blow broken the tibia and fibula. Dr. Hogg was severely taken to task by the learned judge, who accused him of coming to the Court with his mind occupied with preconceived judgment, and in consequence of this the Doctor's expenses were disallowed. Mr. Baron Huddlestone may be learned in common law, but, if we are correctly informed, he talked uncommon nonsense upon the subject of surgical injuries. Webster kicked at Holmes; the latter's leg was afterwards found to be broken; therefore, says Baron Huddlestone, the kick caused the fracture. Legally, of course, the accused was responsible for the injury inflicted. We have no desire to extenuate Webster's offence, and it may be that he received a righteous punishment. At the same time we cannot forget that the learned judge, in passing sentence, was apparently largely influenced by his opinion that the savagery of Holmes was to be measured by the fracture apart from a common-sense surgical view of the proximate cause. The aspersion on Dr. Hogg's professional reputation is of far greater moment to him than the loss of the paltry fee that the Court disallowed.

A NEW ARTIFICIAL ALKALOID.

CHEMICAL synthesis has constructed a new alkaloid with the name of oxy-propyl-endi-iso-amylamine. It is produced by the action of the hydrochloride of propyl upon di-iso-amylamine and forms an oily colourless liquid, soluble in alcohol, ether, and fatty bodies, but very little in water. The salts are very soluble. The physiological and therapeutic properties of this body have been investigated by E. Louïse. The toxic dose for a dog is two decigrammes; and for a man weighing 65 kilogrammes, 13 grammes. On the nervous system it acts something like atropine, but its chief feature consists in the production of epileptic seizures of two kinds. In moderate doses this alkaloid may be considered as a powerful cardiac tonic and an energetic stimulant of the circulation and cerebro-spinal centres. In its action on the heart it approaches atropine, paralysing the inhibitory apparatus and heightening the action of the accelerating nerves. It does not influence the cardiac muscle fibre or the intra-cardiac nervous system. Probably it excites the

Digitized by Google

medullary moderating centres of the heart. The cortical representations of the vagus centres are also acted upon, and it may be that this double action accounts for the remarkable augmentation of the intra-vascular pressure and the marked elevation of the temperature of the body in cases of acute intoxication.

THE TEMPERATURE OF THE NEWLY BORN.

So great a change in the mode of life as happens when the fœtus is detached from the mother might reasonably be expected to be accompanied by some variations of the temperature of the body. Authors have made some observations on this subject, but more are wanting before we can arrive at the truth. The conclusions of Eröss are worthy of attention, for they appear to be the result of careful observation. The temperature, always taken in the rectum, attains its highest degree at the time of birth, generally 37·6° C.=99·3° F.; in the course of one or two hours it sinks to its lowest degree, the average being 35·67° C.=96·2° F. Two days after birth it attains its first maximum, which is less than the birth maximum by ·3° C. The fourth or fifth day witnesses the second minimum, which is less than the first by 1·2° C. The temperature rises again on the sixth day after birth, and reaches its second maximum—1° less than the first—by the eighth day. The curve drawn to represent graphically these fluctuations of the corporeal temperature is interesting to study in the light of the nutritional processes. The first fall is clearly due to the excessive discharge of heat not being properly compensated by the production of heat; the subsequent rise must be regarded as the expression of a physiological reaction from the first fall. That the new-born do react to such conditions was proved experimentally by placing infants in cool baths and subsequently observing the effects on the temperature. Besides these variations, which may be regarded as physiological and dependent on changes in alimentation and rapidity of nutrition, pathological disturbances of the temperature of the body may be noted as the result of suppuration about the umbilicus, intercurrent intestinal catarrh, and the like. Greater fluctuations are observed in proportion to the feebleness of the infant. In opposition to Bärensprung and Förster, Eröss finds that the normal diurnal variation reaches its highest point in the morning at from 6 to 7 A.M., and its lowest point at midday from 12 to 1 P.M. The evening temperature between 6 and 7, and the night temperature between 12 and 1 A.M., are found to give a mean, and not to be maximum and minimum respectively. These latter conclusions certainly require to be investigated afresh.

INJURIES TO THE POLICE DURING THE RECENT DISTURBANCES.

WE have been favoured by the Chief Surgeon of the Metropolitan Police with a short summary of the injuries received by members of the force who were on duty in or near Trafalgar-square on Sunday, Nov. 13th, during the disturbances. In many instances it was not possible for the men to say what kind of weapon was used, but some of those recognised may be mentioned, such as life preservers, a piece of gas pipe, an iron bar, sticks, stones, and kicks from heavy boots. One was stabbed by an oyster-knife, and more than one knocked down and trampled upon. Altogether about 73 are known to have been injured. Injuries of the head, scalp wounds, and contusions 20, injuries of the face 3, head and face 7, neck 2, chin 2, eye 5, shoulder 1, elbow 1, head and hand 1, hand 1, abdomen 2, abdomen and chest 1, thigh (fall of horse) 1, leg 9, knee 4, foot, knee, and back 1, general contusions 4; wounds of eye 1, lips 1, finger (bitten) 1, shoulder (punctured) 1, knee 1; sprains of wrist 1, fingers 5; fracture of nasal bones 1; dislocation of forearm 1; slight concussion 1. Several of these injuries were attended to on the spot, others were treated at the nearest hospital, and others by the divisional surgeons. There was no instance of bullet wound.

THE CONVERSION OF BENIGN GROWTHS OF THE LARYNX INTO MALIGNANT.

AT the recent Congress of German Naturalists and Physicians Professor Schnitzler read a paper upon the subject of the Malignant Degeneration of Benign Growths in the Larynx. He first described a case of epithelial carcinoma with secondary growths in the lymphatic glands and pleura, in a patient who some months previously had been operated on for papillomata, the recurrence of which had been treated by cauterisation. The patient subsequently came under Professor Schnitzler's care with symptoms of perichondritis, but the carcinomatous nature of the disease was recognised, and the supervention of pleurisy some weeks later was considered to be due to a diffusion of the malignant disease. This diagnosis was confirmed after death, when, besides the laryngeal and pleural carcinoma, there were found necrosis of the thyroid cartilage and gangrene of the right lung. Professor Schnitzler remarked upon the rarity with which benign tumours take on malignant characters, he having seen such conversion only three times among hundreds of cases of laryngeal papillomata. He left undetermined the question whether the operations and frequent cauterisations induced the malignant disease, and said that endo-laryngeal operations upon papillomata should be discountenanced on this ground. He also spoke of the difficulty in the differential diagnosis between benign and malignant growths, as well as between laryngeal syphilis and carcinoma. Dr. Morelli related the case of a man whose larynx was so blocked by papillomatous growths as to necessitate tracheotomy prior to a thyrotomy, with complete ablation of the new growth and galvano-cauterisation of the laryngeal wound. The patient left apparently cured, but wearing the tube. After the lapse of a year he returned with evident carcinomatous degeneration of the papilloma, which filled the larynx to the level of the tube, which was partially displaced and blocked by it. This was the only case of the kind that Dr. Morelli could recall within a period of nearly ten years. Dr. Seifert referred to a case published by Böhmer, where papillomata (histologically examined) had been treated by Professor Gerhardt and himself for a year, but which passed into carcinoma, for which extirpation of the larynx was practised; but the patient did not long survive the operation.

UNOFFICIAL PHARMACOPŒIAS.

IT is always satisfactory to the regular practitioner when he can confine the choice of his remedies within the bounds of the British Pharmacopœia. But it must be allowed that many medicines have achieved a decided and meritorious reputation before they reach a place in that honoured but somewhat slow volume. Indeed their appearance in it is the recognition of a reputation already made. Nay, more, it is desirable that new medicines should be well tried before they are admitted into the Pharmacopœia. During this stage of their history it is very important that the profession should have some knowledge of the best way of using them, and of the preparations in which they may be more safely pleasantly, and advantageously administered. Let us take, for example, the case of the drug strophanthus, the action and uses of which have been so brilliantly and laboriously studied by Professor Fraser over a period of fifteen years. Professor Fraser brought his investigations to a most practical issue two or three years ago, and enriched thera-

Digitized by Google

peutics with a new and powerful remedy, but not in time to secure recognition in the Pharmacopœia of 1885. Many practitioners are using strophanthus, or thinking of using it. But they will look in vain for any notice of it, or of any preparation of it in the official list of drugs and preparations. A list of drugs and preparations that, though new and unofficial, are still to a certain extent wanted by the profession, is a real desideratum, for meeting which we must look largely to practical and scientific pharmacists. In 1886, at the British Pharmaceutical Conference, a committee of its members was appointed to prepare a formulary of unofficial remedies. As we announced in our issue of Sept. 10th, it has now produced such a formulary, published by Messrs. Churchill, containing thirty-seven formulæ for the preparation of new drugs or old drugs in new forms. The Medical Council has given power to a committee to do similar work. But it will necessarily move more slowly and view the matter from a somewhat different standpoint.

TEMPERANCE ON SEA AND LAND.

THE virtual suppression of floating grog-shops by common consent of the Powers bordering on the North Sea is a step which must give rise to very general satisfaction. The evils connected with their use and the need of reform had come to be widely recognised before the work of eradication was taken in hand. We may therefore feel assured that the action of the covenanting Powers in this matter will be justified by its results. On land, the advantages of sobriety are everywhere apparent. At sea, the necessity for its observance is at least doubled, as far as concerns the individual immediately affected. There danger is not only common, but is apt to be as various and as sudden in its appearances as the movements of the shifting elements from which it arises. A drinking seaman, if he passes the vague limit of moderation, is in such a case but little better than the waterlogged and derelict vessel, and has become an actual peril to those who sail with him. Any who may be disposed to complain of the new regulations, as affording an instance of illiberal and grandmotherly legislation, must take into account this latter aspect of the question. The interest of the temperate and the desires of the intemperate are here, by the special conditions existing, brought from time to time into inseparable, and it may be fatal, opposition. Hence, in part at least, arises the need of interference by third parties. Another point must not be forgotten. Adulteration is, we cannot doubt, regarded with equal favour by unscrupulous publicans afloat and by men of the same type and calling on shore. There is, however, this practical difference between the two cases: a fairly efficient supervision can without much difficulty be exercised over the defaulting landsman; at sea there must be, to say the least, considerable facility for evasion under any system of inspection. The abolition of the floating public-house will probably prevent much "bad stuff" from reaching the fishermen of the North Sea. With regard to the liquor trade in the coast fisheries, each of the contracting Powers will exercise a separate jurisdiction. Restrictions conceived in the same spirit as those already agreed to will no doubt be imposed, the traffic in this case, with its attendant evils, being but the slightly modified counterpart of that which has till now been carried on at a greater distance from land. The uselessness of this traffic to any but the publican is apparent when we reflect that stimulants amply sufficient for all possible requirements can be taken on board a smack before she leaves for the fishing station. As an example of an effort in the same direction as that we have been discussing, we may mention our own Truck Amendment Act. The clauses of that measure which deal with the payment of wages to farm labourers expressly provide that payment for work shall in no place take the form of an offer of intoxicating drink. It is to be regretted that hitherto custom has in many cases proved stronger than the law; but it is also satisfactory to note that there is an increasing disposition on the part of both farmers and labourers to carry out the provisions of the Act in this important particular. We are also reminded, in a letter by Mr. John Abbey, that the Royal Agricultural Society in 1884 pronounced very decisively against the drink payment, and asserted that labour should be paid in money only. There is, as might have been expected, substantial evidence to show that work is better done when intoxicants are left out of the daily provision than when they are consumed. Workmen on farms have in very many instances shown a prudent consciousness of this fact by adopting, in place of alcoholic drinks, the simplest and cheapest non-intoxicating beverages.

THE ORIGIN OF THE SUPERIOR FACIAL NERVE.

IT is well known that in cases of hæmorrhage and softening of the brain the resulting facial paralysis respects nearly always the orbicularis palpebrarum innervated by the superior part of the facial nerve. In bulbar paralysis a similar exemption of these muscles is also observed. M. Mendel has addressed himself to the study of this subject, and gives the following facts experimentally ascertained. Extirpation of the muscles innervated by the inferior facial nerve, if accomplished on new-born animals, always causes an atrophy of the nucleus of origin of the facial nerve. Extirpation, in a young rabbit and two young guinea-pigs, of the muscles of the eyelids and forehead gave the following result at the end of three months in the rabbit and ten months in the guinea-pigs. The ocular bulb was found to be intact, and so were the trunk and nucleus of the facial nerve. On the other hand, the three brains presented an atrophy of the posterior part of the nucleus of the oculo-motor nerve. The atrophy was not only manifested in the dimensions, but also in the number, of the nerve cells. These experiments seem to prove that in the rabbit and guinea-pig the superior facial nerve has its origin in the nucleus of the third nerve. Is it possibly the same in man? In one case of ophthalmoplegia of central origin the muscles to the eyelids were also paralysed. At present the course of the fibres is not known in these animals, but Mendel thinks they traverse the posterior longitudinal system. The different origin of the bundles of the facial nerve is not surprising, for a similar occurrence takes place in other peripheral nerves.

SANITARY DEFAULT AT FULBOURN.

THE Rector of Fulbourn, near Cambridge, and within the district of the Chesterton rural district, has a sorry tale to tell of disease and maladministration. For five years enteric fever has off and on been prevalent in the village, and for the same period the medical officer of health has persistently but ineffectually urged improvements in dealing with the sewage of the place. In 1883 Mr. Spear of the Local Government Board visited the village and suggested immediate remedies; and in 1886 his colleague, Dr. Airy, went down, but his report, like previous ones, "was, in its turn, shunted." From August to December thirty-eight attacks with nine deaths occurred, and the authority were urged to do something beyond the adoption of mere palliative measures. But notwithstanding all this, fever is still in the place, and it is stated that things must remain so until the causes leading to its production and spread are removed. We have no definite information as to the sort of action that has been taken at Fulbourn; but it seems quite evident that the sanitary authority have not done their duty in the removal of obvious causes of disease and death, and that the inhabitants of the place have a right to demand such permanent remedies as shall prevent a recurrence of further fever spread amongst them so far as this

Digitized by Google

is preventable. This is probably one of the cases in which it becomes a plain duty on the part of some who are strong enough to bear the burden of such action to make definite and formal complaint to the Local Government Board, under Section 299 of the Public Health Act, that the authority have made default. Without that, it seems that the central authority can do no more than they have done, but with a formal complaint before them they have very wide powers of compulsion, and there are many cases in which those who set these powers in motion deserve the highest thanks of the community which they thus serve.

SMALL SOCIAL VICES.

A CORRESPONDENT very sensibly directs attention to the influence exercised by some of the niceties of modern life upon the physical condition of young women at the present day. Without adverting to such grave excesses as the free use of alcohol and of toxic remedies, he instances incessant tea-drinking, sipping eau-de-cologne, and addiction to sensational novel-reading as examples of the prevailing spirit of self-indulgence. There is considerable force in his observation that we may be disappointed in the result if girls, who have in these and similar matters been allowed to regard their wish as their ideal, should at any time have to assume the responsibilities of motherhood. The practices to which he refers are, happily, counteracted in many cases by a native strength of mind and body, or by other habits of a more wholesome character. Still, it must be allowed that they are not in themselves conducive, but rather injurious, to health. They are part of a general tendency to luxurious living, which is not peculiar to one people, century, or sex, and to which we, as a prosperous commercial nation, have too readily become subject. The means of correction are not to be found in Pharmacopœias or in regulations as to the safest methods of indulging the petty cravings of selfish desire. The real remedy will be found in a return to simpler or less artificial usages, and in the increasing recognition of the value of some guiding purpose even in the leisure and the diversions of our lives. A general understanding of sanitary principles would also assuredly do much to assist the formation of a just estimate by the general public of what is and what is not calculated to favour the healthy growth of mind and body. These principles are now happily becoming better and more widely appreciated than formerly. The evils associated with such vices of civilisation as the social customs we have referred to stand, therefore, a fair chance of great limitation, if not of extirpation, when the verdict of common sense thus instructed will have been pronounced upon them.

CHOLERA ON BOARD THE STEAM-SHIP "GOVERNOR."

ON November 11th the steam-ship *Governor* entered the river off Liverpool, having had cholera on board. One man sickened on October 2nd, two days after leaving Calcutta, and died on October 4th; a second man sickened just after, and he rallied, but he ultimately died on October 12th. There were also several cases of diarrhœa on board, but there having been no sickness for three weeks before reaching Liverpool, Dr. Stopford Taylor allowed the vessel to go into dock. The most interesting feature of the story is the fact that the vessel was allowed to pass the Suez Canal "under strict quarantine," and this apparently at a time when she was not free from choleraic sickness. This action, which has now several times been repeated, seems to foreshadow the abandonment of the vexatious and dangerous system of ordering suspected and infected ships to return to Tor, and there to discharge their crews and passengers at an unhealthy lazaret in the Arabian desert.

IMPORTANT DECISION AS TO THE ISOLATION OF INFECTIOUS PAUPERS.

A VERY important question relating to the isolation of the infectious fevers has been raised at Leeds. The sanitary committee of the Town Council claimed the right, if they received paupers into their hospital, to charge the guardians with their maintenance. The guardians of the several unions concerned refused to make the necessary payment, and yet insisted on sending cases into a hospital which had been provided for all inhabitants of the district; they also sought the opinion of the Solicitor-General, who stated that they were right in their contention. The Town Council, having this legal opinion before them, met on the 15th inst., and they now declare that they are not prepared to accept it as sound, but they have written to the guardians to say that without prejudice to the general question, they have decided to receive for a period of one year such pauper patients as may be *bonâ-fide* inhabitants of the borough, after which date they will reconsider their action. They further state that, in adopting this course, they in no way acquiesce in the contention of the guardians, and that they have been actuated by a desire, if possible, to avoid costly litigation. It is much to be regretted that so important a matter should be left in so undecided a state; for if all Poor-law guardians have a right to send into hospitals provided by sanitary authorities such pauper cases of infectious disease as they see fit, it seems obvious that the right to refuse admission on the ground of social status is at an end, and the question of the nature and extent of the hospital provision to be supplied by sanitary authorities will have to be dealt with in a very different way from that hitherto adopted.

ATHETOSIS.

DR. ALFREDO RUBINO of Naples discusses, in some thoughtful articles in the *Riforma Medica*, two cases of athetosis which have come under his care. Both followed hemiplegia due to embolism, and one of the two was associated with multiple paramyoclonus (a muscular spasm differing but little from chorea). The fact of the athetosis and the paramyoclonus coexisting appears to point to a common origin of the two affections, which may be, as Dr. Gowers has suggested, in post-hemiplegic spasm generally, a peculiar condition of molecular instability of the grey substance of the brain, which, however, is not recognisable with the means at present at our command. The lesion which causes athetosis may, Dr. Rubino thinks, be situated at any point of the cerebral motor elements; but it is usually in the psychomotor centres of the cortex, in the inner capsule or in the optic thalamus. He does not view athetosis, generally speaking, as forming a pathological entity in itself, but considers it, like hemichorea, which is only another variety of post-hemiplegic spasm, as a mere development of a preceding affection—hæmorrhage, embolism, inflammation, atrophy, &c. Nevertheless, he is prepared to admit that some cases may be true essential neuroses, especially as it is sometimes double; and this may, perhaps, bear the same relation to the more usual single form that chorea does to hemichorea.

INQUEST EXTRAORDINARY.

AN inquest was held before Mr. W. E. Baxter on November 19th touching the death of Anne Gieser, aged thirty-three. The deceased, whilst under the influence of drink, was struggling with her husband, when she fell backwards to the ground. The husband alleged that owing to the fall a hairpin was driven into her head to the depth of five inches. A medical witness deposed that he could find no trace of a puncture, and that in his opinion death was due to syncope. We can quite under-

Digitized by Google

stand all this; but we were not prepared for the coroner's statement that the medical men were unable to discover the aperture of entry of the bullet fired into Mr. Gold's body by the murderer Lefroy. It is true a bullet wound may close up, as it were, and not be recognised on casual observation; but surely a careful examination could not fail to detect the lesion, nor is it probable that the channel made by the passage of a hair-pin into the flesh would escape discovery. The report of the inquest reads something like a romance. It was consistent, however, in this, that the verdict returned by the jury agreed with the narrative of Lefroy's case made by the coroner. It ran thus: "Death from failure of the heart's action, accelerated by the prick of a pin."

SIR WILLIAM GULL.

WE learn that Sir William Gull left Pitlochry for his residence in London on Wednesday at 2 P.M., arriving in Brook-street at 5 A.M. on Thursday morning. Sir William, we are glad to announce, made a most satisfactory journey. His general health is good, and improvement in the special symptoms is maintained. The London and North-Western Railway Company sent a special carriage for Sir William's accommodation, and made every arrangement in their power for his comfort and convenience during the long journey from the north.

THE INTESTINAL ORIGIN OF CHLOROSIS.

AN interesting contribution by M. Duclos has been made to the *Revue Générale* (No. 37) on this subject. He considers that chlorosis is eminently a result of auto-infection, a true poisoning resulting from the retention and putrid decomposition of fecal matters in the intestine. As a rule chlorosis is preceded by and associated with constipation, but this rule is not without exception. Sometimes the poisoning takes place rapidly; the putrid decomposition may be active or the intestinal absorption may be more or less complete; and in harmony with these differences the varieties of chlorosis may be observed; even fever and endocarditis may arise as a result of such auto-infection. Everyone admits the importance of overcoming intestinal inactivity in these cases, even though they do not feel disposed to accept M. Duclos' theories.

HARVEIAN SOCIETY.

A COURSE of three lectures on Lupus, by Mr. Hutchinson, will be commenced at the rooms of the Harveian Society on Thursday next. We are informed that these lectures will concern general pathological problems as to the real nature of many maladies cognate with the more typical forms of lupus, more especially in their relations with tuberculosis and scrofula, and that they will not be addressed specially to dermatologists. The Society meets at Stafford Rooms, Tichborne-street, Edgware-road, at 8.30.

ŒDEMA NEONATORUM.

ŒDEMA NEONATORUM, though closely associated with sclerema of the newly born, also presents considerable analogy with phlegmasia alba dolens according to M. Léon Dumas, who perceives the analogy not only in symptoms, but also in etiology and pathological anatomy. Nevertheless, thrombosis of veins had not hitherto been described in cases of œdema neonatorum. M. Dumas of Montpellier has discovered a thrombus in both femoral veins in a fatal case of this affection. Whilst awaiting fresh observations to confirm this view, M. Dumas speculates on the possibility of spontaneous venous thrombosis occurring in the cachectic condition common in many new-born infants, in whom respiration and circulation are not easily established in full perfection.

H.I.H. THE CROWN PRINCE OF GERMANY.

WE are authoritatively informed that Sir Morell Mackenzie has received a highly satisfactory report from Dr. Krause. The lumen of the larynx is practically entirely free, and the general health could not be better.

DIPHTHERIA AT SHIRLEY.

THE difficulty which we indicated of proving a connexion between diphtheria at Shirley and the nuisance from the sewer ventilators is well shown by the contradictory statements that have appeared in the public press. But, on the whole, it seems clear that there is an offensiveness connected with the sewers that ought not to exist, and the most recent explanation of it is the abnormally high temperature which the sewer contents exhibit, owing to the discharge into the culverts of boiling water from a brewery. It is a great pity that the report of the Government inspector is not asked for by the complainants. Its perusal might clear up some of the difficulties connected with the case.

EPIDEMIC OF LEAD-POISONING DUE TO FLOUR.

IN the month of June, 1887, more than 100 individuals of all ages, inhabiting the villages of Villemontois, St. Maurice, and Lentigny, presented simultaneously a peculiar series of symptoms which proved to be due to lead poisoning. The case has been investigated by MM. Bertrand and Ogier, who came to the following conclusions:—That leaden vessels employed in transferring meal may be a cause of serious lead poisoning. That the lead enters the system in the form of sulphide. The sulphur must have been derived from fissures in the grindstones which had been obliterated by the use of sulphur.

SMALL-POX IN THE PERTH INFIRMARY.

DR. LITTLEJOHN sees no harm in the directors of the Perth Infirmary retaining in their institution such cases of small-pox as arise in it; and apparently the separate pavilion will in future be used for such purposes. As we have said before, other similar institutions have not, even with detached pavilions and isolation buildings, felt this to be a safe course; but so long as the inmates of the Perth Infirmary are well enough, and are willing, to be revaccinated on such occasions, danger is of course practically removed. But such favourable circumstances may not always be experienced.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda-Pesth.—Drs. Eröss and Ottava have been appointed lecturers in Diseases of Children and Ophthalmology respectively.

Innsbruck.—The Professorship of Pathological Anatomy having been declined by Professor Weichselbaum, Dr. Pommer has been appointed to give the lectures for the present.

Kiel.—It is proposed to establish a Professorship and an Institute of Hygiene.

Marseilles (école de plein exercise).—The Municipal Council is endeavouring to get the Medical School raised to the rank of a Faculty.

St. Petersburg.—Dr. Shudnovsky has been promoted to be Professor of Diagnosis.

Seville.—Señor Moresco has been nominated Professor of the Diseases of Children.

Strasburg.—Professor Kussmaul, being about to retire at the end of the current winter semester, will probably be replaced by Professor Naunyn of Königsberg.

Valladolid.—Señor Roa has been nominated Professor of the Diseases of Children.

Zaragossa.—Señor Borovio has been nominated Professor of the Diseases of Children.

Digitized by Google

MR. S. HAMILTON CARTWRIGHT has recently sailed for Australia, where he is about to be married. He has resigned the Professorship of Dental Surgery at King's College, and the Dental Surgeoncy to King's College Hospital, which he has held for the past twelve years, in succession to his father, Mr. Samuel Cartwright. He has also given up all intention of resuming dental practice, but may probably return to general medical work. A large number of friends assembled before his departure to bid him adieu.

THE great St. Petersburg physician, Professor Botkin, is now in Paris, where, accompanied by his son, Dr. S. Botkin, he has been visiting the hospitals. He is, of course, receiving every mark of attention, and when his name is mentioned to the students he is greeted by an ovation.

A CONGRESS of physicians and veterinarians, with the view of discussing the subject of tuberculosis in man and in animals, is announced to be held from July 25th to the 31st, in the rooms of the Faculty of Medicine, Paris. Professor Chauveau will preside.

MR. FRANCIS GALTON'S proposed lectures at the South Kensington Museum on Heredity and Nurture, which were postponed on account of his illness, are now announced for the Saturdays, Nov. 26th, Dec. 3rd, and Dec. 10th, at 4 P.M.

AT a meeting of the Council of Queen's College, Birmingham, held on the 17th inst., Mr. Lawson Tait was elected Professor of Gynæcology, and Mr. T. H. Bartlett Lecturer on Operative Surgery.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

TUESDAY, NOVEMBER 22ND.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

AFTER some formal business, including the introduction of new members (Sir George Macleod in the place of Dr. Fergus, and Dr. Samuel Wilks as a representative for the University of London), the PRESIDENT delivered the following address:—

I deeply regret that upon the first occasion on which it is my privilege to open a session of this Council my earliest words must be expressive of our common sorrow at the unexpected death of the late Dr. Andrew Fergus, who, as the Crown member for Scotland during the past ten years, had gained the esteem of all his colleagues as a sagacious councillor and a genial friend. The serious illness of Sir William Gull demands an expression of sympathy on our part towards one who was for twelve years a zealous Crown member for England, and has since then been for a brief period the representative of the University of London. To this I am confident I may add your earnest hope that his progress towards recovery may lead to his complete restoration to health. The two seats on the Council thus vacated will doubtless be worthily filled by the well-known members who have just been formally introduced. Since the last meeting of the Council, the business of the office, whether current or occasional, has been so arranged and carried on that no important arrears have been permitted to accumulate. It will have been noted by you that, as indicated in the summons, this present session of the Council may be regarded primarily as brought together for the discussion and settlement of certain specified subjects. This view has been adopted in accordance with what I have understood to be a general desire, that the autumn meeting of the Council, in November, should be limited, so far as found to be practicable, to the consideration of all questions connected with the completion and rectification of the Medical and Dentists' Registers, including the investigation and decision of cases involving the possible removal of titles or names, or of both titles and names, from the Registers, under the penal clauses of the Medical and Dentists Acts; whereas questions appertaining to education and examinations might be relegated to the spring meeting of the Council in May, which will, however, be summoned for "general business," and so be formally competent to deal also with registration work. It is believed that such an allocation of the exceedingly varied duties of the Council may contribute to the satisfactory and economical despatch of its business. To prevent misconception, and to anticipate possible queries, it is well for me to add that this arrangement in no way precludes the consideration of any subject not included in the terms of the special summons, provided that a majority of the Council should be in favour of such a proceeding. Indeed, one important additional subject has already offered itself, which will require the decision of the present meeting of the Council—namely, an application from the Society of Apothecaries of London relating to a proposed examination for the grant of a diploma in Public Health. With this addition, it is hoped that the following sketch will be found to comprise all important subjects demanding immediate attention. 1. The adoption of the amended Standing Orders is a necessary, but I trust a merely formal, part of our present duty. These have undergone revision by myself, by the Registrar, and by a special committee, and have been finally submitted to and approved by the Executive Committee. The chief alterations in them relate to the times of meeting of the Council, to the constitution and election of committees, and to the appointment and duties of the inspectors. A few obsolete orders have been omitted. Some slight additions or emendations may still have to be introduced, in the event of any further recommendations from the Finance Committee or the Income and Expenditure Committee being adopted by the Council. 2. The inevitable, but I believe not embarrassing, subject of finance will be brought to your notice in a report to be presented to you by the senior treasurer. 3. A brief report on the question of "unqualified assistants," to be submitted to you by Dr. Chambers, will, it is hoped, be adopted by the Council and entered on the Minutes, with a view to its gaining subsequent useful publicity. 4. An important document relating to the registration under the Medical Act, 1886, of foreign degrees in medicine, held by registered practitioners, and obtained previously to the appointed day—viz., June 30th, 1887,—will be brought forward by Dr. Humphry for adoption by the Council. It is the result of prolonged and elaborate inquiry and correspondence. The information obtained has been tabulated by the Registrar, and certain recommendations prepared by a few members of the Executive Committee have been considered and agreed to by that body. Several schedules are appended to this report. Should the recommendations therein contained be adopted by the Council, it will be further proposed that the titles belonging respectively to the registered practitioners named in Schedule A may, on payment of the proper fee, be forthwith registered. This form of procedure becomes necessary, as the Council is the authority to which, under the Act, that duty is assigned. In the near future applications for this form of registration will cease, and the recognition of the validity of the few outstanding claims may, after due inquiry, be properly delegated to the Executive Committee, subject to report to the Council. 5. I must absolutely defer, for the consideration of the Council only, the unfortunately numerous cases arising under the penal clauses of the Medical and Dentists Acts; but I may make this comment, that their number on this occasion is the necessary consequence of their being all reserved for consideration at this session of the Council. 6. In view of the complications which arise out of the diversity of disciplinary powers and practice amongst the numerous authorities capable of granting registrable medical qualifications in the United Kingdom, I desire to suggest to the Council the appointment of a special committee to collect authentic information on this important subject, and, after consultation with the legal advisers of the Council, to present a report at our next meeting, embodying the facts so ascertained, and, if found practicable, offering recommendations simplifying our proceedings in such cases. If not exceeding my privilege as your president, I would venture to suggest, in reference to this subject, four important propositions: First, that each qualifying authority should be the guardian of its own honour, and should primarily exercise

Digitized by Google

the function of deprivation of its qualifying degree, diploma, or licence. Secondly, that all the qualifying authorities should have in this respect the same rights and powers conferred upon them by Act of Parliament or by special statute, the Universities also being included so far as their medical degrees are concerned, inasmuch as these convey the right of entry into a profession. Thirdly, that there should be granted to the licensing bodies a power to proportion the penalty to be inflicted to the gravity of the offence committed; such, for example, as by admonition and the requirement of a guarantee for the future, or by either a temporary or a permanent deprivation of a qualification. Fourthly, that, except under certain very restricted conditions, the withdrawal of a qualification, or the subsequent restoration of the same by the authority concerned, should be followed, as a necessary consequence, by its removal from, or its subsequent restoration to, the Medical or Dentists' Register, as the case may be. These and other propositions would, I submit, be appropriately dealt with by a specially appointed "Discipline Committee," which should report as early as possible to this Council. 7. Finally, I have to suggest that, now that we are assembled together, an opportunity exists for the members of the two Standing Committees on Education and Examination to indicate to their respective chairmen subjects for inquiry, consideration, and report, in readiness for the ensuing spring meeting of the Council. With these introductory observations, I now commit to your hands the important work of the present session.

Communications were received from the Royal College of Surgeons in Ireland and from the British Dental Association with reference to the case of Mr. H. T. Partridge and his removal from the Dentists' Register. The communications were referred to the Dental Committee for inquiry and report.

Dr. HUMPHRY called attention to the marble bust of Sir George Paget which had been presented to the Council by some of its members, and which, he said, formed an admirable companion to the bust of Sir Henry Acland presented at the last session. The presentations showed the high esteem in which the two late presidents of the Council were held by those who worked under them.

Dr. QUAIN expressed the thanks of the Council to the gentlemen, especially to Dr. Humphry, for the presentation of Sir George Paget's bust.

The PRESIDENT, on behalf of the Council, thanked the subscribers for the bust.

Sir W. TURNER moved the acceptance of the Standing Orders as revised by the Executive Committee, with the exception of Clauses 5 and 9 of Chapter XI, and Clause 1 of Chapter XVIII.

Dr. QUAIN seconded the motion.

Dr. STRUTHERS thought that the whole chapter relating to finance should be omitted. The question of the remuneration to members of the Council might give rise to a discussion, and had better be left until the Finance Committee's report was received.

Sir W. FOSTER wished to know in what particulars the old Standing Orders had been altered.

The PRESIDENT said that in the first instance the old Standing Orders were printed on one side of the page and the proposed new ones on the other.

The following report from the Committee on Unqualified Assistants was then read:—

"Since the publication, under the authority of the Executive Committee, given on July 25th, 1887, of the resolution passed by the Council on April 21st, 1883, relating to the misemployment of unqualified assistants, a number of letters on the subject, chiefly marked 'Private,' have been received by the Registrar. From these communications—which may be consulted by members of the Council, and which will be preserved for further reference,—from notices in the newspapers, and also from common report, it is evident that magistrates, coroners, County Court judges, and other representatives of the public sense of justice, as well as medical men themselves, are becoming alive to the professional misconduct of registered practitioners who place patients under the sole charge of unqualified assistants. The administrators of the law regard as implicit fraud any claim of payment for the service of such subtitute assistants, when it is represented as 'medical attendance.' This fact is encouraging, for when it is found that the owner of a 'branch practice' cannot get a claim allowed for the services of his unregistered 'substitute,' and, moreover, that the protection of a 'cover' does not enable the unqualified practitioner to recover charges, these two kinds of irregular practice will probably not long continue to exist in this country. It is worth the attention of the Council, and especially of that part of it which constitutes the Education Committee, that one excuse made for the employment of unqualified assistants is the fact that young medical men recently qualified are often found incompetent to treat common diseases, and are, therefore, so far unfit to take sole charge of the sick. Modifications of the educational curriculum, which would render imperative on the student to obtain a more complete clinical knowledge and a greater acquaintance with the details of practice by personal intercourse of patients, would be viewed with favour by members of the Council and of the profession generally."

Dr. CHAMBERS, in moving that the report be received and entered on the Minutes, said the committee had never met, the report having been drawn up by correspondence. They were so completely in agreement that it was not necessary for them to meet. It had often been remarked by jurists that the best statutory laws were those the penalties of which had never been enforced, acting, as they did, by indirect influence. That was the way in which the resolution of the Council with regard to the employment of unqualified assistants had acted. A very considerable number of practitioners in the North, who had formerly employed them, had given them up, being men of respectability and position in society, who valued their good name. There were, however, others who braved out the resolution of the Council. Unfortunately, the worst cases had not been brought forward, and their offences had been condoned on the promise not to infringe the rules again. It would be very desirable to get hold of some really bad cases. When evidence was obtained that certain men habitually employed unqualified assistants, the Council would, no doubt, know what to do with them. Several practitioners had stated that they could not put qualified men in charge because they were unequal to the treatment of ordinary diseases.

Sir W. FOSTER seconded the motion. There were, he said, two classes of unqualified assistants employed by medical men throughout the country. It would be perfectly impossible for the Council to interfere with the legitimate unqualified assistants, because, if they did, those men would probably be taken on under the name of apprentices, and the Council did not wish to stop the unqualified practice which went on under the eye of qualified medical men. They did, however, object to those who only escaped the law by the use of a "cover," and he hoped the Council would take the most vigorous action to put down that nuisance.

Mr. TEALE thought that certain recent actions at law had gone a long way towards settling that question. In one County Court the other day charges for an unqualified assistant were disallowed, and he had received a circular inviting medical men to attend a meeting in order to move Parliament on the subject, so that the persons concerned were keenly feeling the effect of the decisions.

Dr. DUNCAN felt bound to express his difficulties about this subject. What was an "unqualified assistant"? Until that was explained he must feel doubts about the propriety of the report. Although no money was made by it, he employed hundreds of "unqualified assistants" in one of the most important duties of the profession. He had 2000 midwifery cases annually under his charge, all done by "unqualified assistants," and there was no word in the report to prevent his being taken to a court of law as an employer of such assistants. He was in accord with the general object of the report, but he disliked that the Council should blacken its own children, and tell the public that young medical men were not fit to attend ordinary cases. It would be very remarkable if they committed themselves to any such doctrine.

Dr. HERON WATSON said that in May, 1883, a definite report was presented to the Council by a previous committee on the same subject, and in the discussion it was distinctly brought out that there was to be no interference with that legitimate supervision of pupils in the conduct of cases which was required for the purpose of training and for dealing with the sick and necessitous poor. Many instances, however, were brought forward of practitioners employing assistants who practically took full charge of the cases, and that seemed to be absolutely discreditable to any member of the profession.

Mr. MACNAMARA said there was a very important distinction between "unqualified assistants" and the class

Digitized by Google

which Dr. Duncan had alluded to. In the latter case the assistant paid for the privilege of learning his profession, whereas in the former the public paid.

Dr. STRUTHERS said the last paragraph of the report contained a censure on young medical men, who, though highly educated, were of course unfitted to attend to certain diseases.

Mr. MITCHELL BANKS also thought the last paragraph ought to be struck out.

Dr. GLOVER said the subject of attention to the more common diseases had been referred to the Education Committee, from whom he hoped they would receive a very interesting report; but he objected to the last paragraph being deleted. It simply alleged that it was a common excuse for the employment of "unqualified assistants" that young qualified men were incompetent to take charge of ordinary cases. One of the defects of medical education was that the student had no chance of learning to deal with scarlet fever, small-pox, &c. It was a very common thing for patients to die without the principal ever seeing the cases. One instance had only just been reported to the Executive Committee. The patients were under the sole charge of an "unqualified assistant," and the principal, who resided at a distance, only came in at the death to give a certificate. Such practice had been severely condemned in Parliament, by the judges, and by the Council, and he hoped that that condemnation would not be retracted.

Mr. BRUDENELL CARTER thought the objection might be met if the words "is the fact" were altered to "rests upon the assertion."

Mr. MCVAIL considered the report a very valuable one, particularly in relation to the resolution passed last February, that it was necessary to reconsider the question of pupilage.

The further discussion was adjourned for a time, the hour having arrived for the attendance of the Solicitor in connexion with the following cases.

The SOLICITOR said the case of James McCully came under the 29th Section of the Medical Act of 1858, and he produced a certified copy of the conviction at the Central Criminal Court, to the effect that he had been sentenced to imprisonment for two years, without hard labour, for writing and publishing a scandalous and defamatory libel.

Strangers were directed to withdraw, and on their readmission,

The PRESIDENT announced that the Council, having considered the case of James McCully, have arrived at the conclusion that he has been proved to the satisfaction of the Council to have been convicted of misdemeanour, and that the Registrar be directed to erase his name from the Medical Register.

The SOLICITOR said a summons had been sent to Mr. Thomas Ormsby Wiley of the Isle of Wight to attend the Council, and a letter had been received from his legal adviser stating that he had gone abroad. The evidence he had to bring before the Council was a newspaper report of the proceedings in the Divorce Court, and a statutory declaration by the petitioner that the report was true.

Strangers were again directed to withdraw, and after the Council had deliberated for a few minutes,

The PRESIDENT announced "that, in the opinion of the Council, Thomas Ormsby Wiley has committed the offence charged against him; that the offence is, in the opinion of the Council, infamous conduct in a professional respect; and that the Registrar be directed to erase his name from the Medical Register."

The discussion on the Report on the Employment of "Unqualified Assistants" being resumed,

Dr. MATTHEWS DUNCAN said the definition of an "unqualified assistant" referred to by Dr. Heron Watson was not the definition of the Council, and never had been adopted by it. What he (Dr. Duncan) had intended to convey was that they could not condemn "unqualified assistants" without defining what the phrase meant.

Dr. PETTIGREW thought the Report should be referred back to the committee and the last clause expunged. The teaching supplied at the various hospitals was much better in the aggregate than the teaching of any one man, however good he might be. He was disposed to encourage the idea of young graduates taking assistantships before embarking in their own practice.

Dr. LEISHMAN considered the language adopted in the report as somewhat unfortunate. An "unqualified assistant" might be any person who had not a legal title. It was quite possible that an "unqualified assistant" might be capable of taking charge of minor cases, and a practitioner might be perfectly justified in handing such cases to an unqualified assistant. Was he therefore to be branded with "unprofessional misconduct" for "the employment of unqualified assistants"? It seemed to be an unfortunate phrase.

Dr. S. WILKS said there were no doubt certain points in which unqualified assistants might be found wanting. He knew for a fact that men came out from the hospitals without any knowledge whatever of diseases of children, such as measles and scarlet fever. He had conducted examinations for a number of years at the College of Surgeons in conjunction with Dr. Peacock, who never failed to ask the candidate how many cases of scarlet fever he had seen, and a very large proportion of them said they had never seen a case. He had heard of a young man who got prizes and obtained excellent testimonials, in addition to the diploma of the College of Physicians, and then took an appointment as medical officer to a school. A child in that school had an eruption, and in the course of three days twenty children were similarly affected. The medical officer, not knowing what it was, was obliged to ask an old country friend to tell him, and he pronounced it to be measles. He had actually never seen a case of measles before.

Dr. HAUGHTON knew, as a matter of fact, that many students never went near a fever hospital. It was only quite recently that steps had been taken by the great majority of the licensing bodies to see that no men were allowed to practise without having ever seen a case of childbirth. It was only a short time ago that some of the army surgeons rather prided themselves on never having seen a case of midwifery, but the Act of 1886 now required surgery and midwifery as well as medicine. He should support most cordially the last paragraph of the report.

Dr. BANKS said his experience had been the same as that of Dr. Wilks, he having seen men who had obtained their diplomas without having seen a case of some of the ordinary diseases, and particularly of scarlet fever. Some time ago he met an army surgeon in consultation about a case of scarlatina, and the surgeon told him that he had never been in a fever hospital and had never seen a case of scarlatina. Students were frequently very industrious in the surgical and medicine departments, but they sometimes feared to go into the fever ward; in fact, on one occasion a young man under examination in the Royal University, when sent to examine a fever case, actually refused to do so. The report referred to assistants of general practitioners, but if it referred to resident pupils in hospitals he should protest in the strongest possible way against it.

The PRESIDENT hoped the Council would adopt the report, striking out the last paragraph. The subject would come before the Council in May, and it would be better not to introduce any debatable matter into the report, which was one of facts, and which if published would do a great deal of good.

The report having been received and entered on the minutes, Dr. CHAMBERS moved and Dr. HAUGHTON seconded its adoption.

Dr. MATTHEWS DUNCAN moved, as an amendment, "That this report, with the omission of the last paragraph, be adopted."

Dr. STRUTHERS seconded the amendment.

Dr. GLOVER hoped that the last paragraph would be allowed to remain, especially after the statements made by Dr. Wilks. There might, perhaps, be some slight alteration made in the wording of the paragraph.

The amendment was then put to the Council, and carried by 16 votes to 10.

On the motion of Sir WILLIAM TURNER, seconded by Mr. TEALE, the report of the committee appointed to consider the question of the registration of foreign degrees in medicine under Section 16 of the Medical Act was received and entered on the Minutes. The consideration of the report was adjourned.

On the motion of Mr. BRUDENELL CARTER, seconded by Dr. MATTHEWS DUNCAN, a communication from the Apothecaries' Society of London, containing the proposed regulations of examination for a diploma in Public Health was received, and entered on the Minutes.

Mr. CARTER then moved: "That the diploma in Public Health of the Apothecaries' Society of London, granted after examination, according to the regulations now received and entered in the foregoing Clause 16 of these Minutes, be reco-

Digitized by Google

gnised by the Council for purposes of registration in the Medical Register, under Section 21 of the Medical Act (1886)." He said the regulations had been framed with extreme care. They provided for a complete examination, and would provide a qualification of great value to members of the profession.

Dr. BRUCE seconded the motion.

Dr. HERON WATSON moved, as an amendment, "That the opinion of counsel on the meaning of Clause 21 of the Medical Act (1886), as bearing upon the application of the Society of Apothecaries of London, be obtained as soon as possible before granting that application."

Dr. MATTHEWS DUNCAN seconded the amendment, which was carried.

The Council then adjourned.

WEDNESDAY, NOVEMBER 23RD.

The Council reassembled at two o'clock, Mr. MARSHALL, President, in the chair.

The first business on the programme was the consideration of the case of Henry Arthur Allbutt, a medical practitioner of Leeds.

Dr. HERON WATSON moved: "That this case be heard with closed doors, in the absence of strangers."

Dr. PETTIGREW seconded the motion.

Sir W. FOSTER thought the wiser course would be to pursue the ordinary course and to hear the case in the presence of the public, and then, as required by its standing orders, for the Council to deliberate upon the case in private.

The PRESIDENT said that he had taken the advice of Mr. Muir Mackenzie and Mr. Farrer, their counsel and solicitor, and they did not recommend that the Council should proceed to any unusual exclusion of strangers at that stage of the case.

Mr. MUIR MACKENZIE having stated his reasons for the advice he had given, the motion was put to the Council, and lost.

Mr. Allbutt was then admitted, accompanied by Mr. Robert Lamb Wallace, who appeared as counsel on his behalf.

Mr. WALLACE asked formally for an adjournment of the case, on the ground that his client had not had proper time to prepare his defence.

Mr. MUIR MACKENZIE submitted that the time given by the summonses to Mr. Allbutt was such as would be considered ample in any legal proceedings. There was no reason for the application.

Mr. WALLACE said the summons was issued on the 9th inst., and owing to absence from home did not reach his client till the 14th, with the result that the brief was not placed in his (Mr. Wallace's) hands till Friday last. He submitted that there had not been ample time granted for the defence to be scientifically prepared and conducted.

Mr. MUIR MACKENZIE said the time given had been more than was granted by the standing orders. He could not advise the Council that sufficient ground had been shown for the adjournment.

Mr. WALLACE said he would withdraw his request for an adjournment, but he asked that the members from Leeds, Mr. Wheelhouse and Mr. Teale, might be requested to withdraw from the Council, as his client had good reason to believe that they were personally prejudiced against him.

The PRESIDENT said it was not possible for the Council to listen to such a request. The request had been made, but the Council could take no notice of it.

Mr. FARRER then stated the case against Mr. Allbutt, which had been brought to the attention of the Council by the Leeds Vigilance Association. Mr. Allbutt was a member of the Royal College of Physicians of Edinburgh, and a licentiate of the Society of Apothecaries of London. The gist of the charge against him was that he had published a book or pamphlet entitled "The Wife's Handbook." The General Council having referred the case to the English Branch Council, who deputed a committee of their body to inquire into the facts, the committee reported "that the pamphlet was extensively sold, and that besides containing much that was offensive to good taste and professionally objectionable, it taught how sexual intercourse might be indulged in without fear of pregnancy supervening, but it did not distinctly recommend that kind of indulgence unless avoidance of pregnancy was advised by the doctor." The seventh chapter was the one that was the most objectionable, the title being "How to Prevent Conception when advised by the Doctor." There were also a number of advertisements bound up with the book, entitled "Malthusian Appliances." The Committee of Inquiry did not proceed further on the supposition that the Royal College of Physicians of Edinburgh was taking steps for the removal of Mr. Allbutt's name from the list of their Members; but in a letter dated June 11th, 1887, the Royal College stated that, seeing that their action could only deprive Mr. Allbutt of one of his two qualifications and that the case was now occupying the attention of the English Branch Council, they proposed to delay taking any further steps until the decision of the General Medical Council regarding the case should be declared. Under these circumstances, the Branch Council for England thought the case was one for the consideration of the General Medical Council. The question to be decided was whether the book was a fair medical treatise or an indecent advertisement, and was it a book so injurious to the public in point of health as well as morals, and so evil in its tendency as regards the profession, that its publication would be considered to be "infamous conduct in a professional respect."

Mr. WALLACE said his client had been charged with a very grave offence, and one which, if proved, would merit severe punishment. He commented very severely upon the way in which the case had been got up by Mr. Lechmore and the Leeds Vigilance Association, and complained of the hardship that had been inflicted upon his client by the change of venue from Edinburgh to London. He was charged with having written an indecent book, and with having attached thereto advertisements of an unprofessional character entitled "Malthusian Appliances"; but what on earth was there unprofessional about Malthusianism? Though he was charged with printing an indecent book, yet for months afterwards they permitted the book to be publicly sold, instead of indicting him at once, as they might have done, in Scotland for issuing an obscene libel. Instead of that the charge had been hung over his head for ten months, and everything had been done to ruin his client. With regard to the advertisements about Malthusian appliances, they were inserted only at such a price as would cover the cost of printing, so that Mr. Allbutt did not issue them for the purpose of monetary profit or with the view of attracting patients to himself. Some of the advertisements were by firms who were well known to be thoroughly respectable, and it could not for one moment be supposed that they did not know the nature of the book. It was manifest that the British public, who were the last tribunal, did not think the work was an obscene libel. In reference to the general tendency of the book, he contended that the limitation of the population was a legitimate subject for discussion.

The learned counsel had not finished his address when the hour of adjournment arrived.

THURSDAY, NOVEMBER 24TH.

The Council met at two o'clock, Mr. Marshall, President in the chair.

The consideration of the case of Mr. Henry Arthur Allbutt was resumed.

Mr. WALLACE, continuing his address, urged that the tendency of the whole book written by Mr. Allbutt was highly moral, and he asked the Council, in any resolution they might come to, to give such an expression of opinion as would give the book the *imprimatur* of the Medical Council. The earlier chapters of the book dealt with the signs of pregnancy and how to keep health during pregnancy. It then proceeded to warn women against the danger arising from an over-prolonged suckling of infants, a practice which was stated to prevail to an enormous extent among the lower classes under the mistaken idea that by so doing they prevented conception, and which was apt to produce blindness in the mother and idiocy in the child. It also spoke strongly against the use of alcoholic stimulants. It then dealt with the ill-effects upon the mother of repeated pregnancies occurring at short intervals. He warned women against the crime of attempting to procure abortion, and then proceeded, in the seventh chapter, which was the crux of the whole matter, to state various methods to prevent conception. Here the question arose whether it was right to advocate the use of such checks, and whether the checks suggested were proper ones. He did not know whether it would be argued that the advocacy of any check to popula-

Digitized by Google

tion was undesirable, but he would certainly undertake to show that such things had been discussed before, and not condemned. Referring to an article which appeared in the *Fortnightly Review*, written by Mr. Montagu Cookson, Q.C., in which the Malthusian theory was advocated and a check suggested, he urged that if the advice was immoral the writer of that article ought to be proceeded against. It had also happened that details of evidence given at divorce trials had been published in the daily press which were quite as suggestive as anything contained in the book now under discussion, and surely, if this was immoral, they, too, ought to have been proceeded against. He protested against the hardship done to his client by singling him out for persecution of this kind. Dealing with the figures representing the birth and death rates of large towns, he submitted that a *primâ facie* case was shown for some means being adopted to check the enormous and totally unnecessary increase of population among the pauper class. He proposed to call competent witnesses to prove the terrible and alarming state of things existing with regard to this constant propagation.

Mr. MUIR MACKENZIE said that would be absolutely irrelevant. There was only one question for consideration, and upon that there could be no evidence—viz., what was the tendency of this work? That was the whole question for the Council.

Mr. WALLACE thought it was most directly relevant. He was trying to prove that this book was written with a moral purpose, with a view of preventing a great evil which was accruing to the State, and the calling of a witness to prove the existence of that evil, and that this book would have the effect of reducing it, was, he submitted, entirely relevant.

Mr. MACNAMARA said it might be taken for granted that the members of the Council were perhaps better acquainted with questions of infantile mortality and with the protective means that had been suggested in the book than any witness that could be called before them.

The PRESIDENT said the Council had no power to examine witnesses upon oath, and therefore their statements could not have additional weight to those made by counsel. Unless the Council authorised him to do so, he must decline to have any witness produced.

Mr. WALLACE said he would withdraw his suggestion. It was alleged in the indictment that this book was sold at so low a price as to bring it within the reach of the youth of both sexes, to the detriment of public morals. It was not alleged that the book was an immoral one, although that was alleged in the Scotch indictment—the Medical Council did not think fit to charge him with that, and so he was charged with having sold it at a low price. Was it meant to be seriously contended that if it had been published at two guineas nothing could have been said against it? The book had now been published for two years, and he challenged the product of any proof that it had done any harm to public morals. He found on personal inquiry at places where it was most likely to be kept for sale that it was not so kept, and at one shop where it was kept it was only sold to adults and to persons supposed to be married. Mr. Allbutt had declined to allow it to be sold in the streets. It was charged that this work contained statements which might gratify the vicious, but was there any surgical work which did not contain material which might gratify the vicious? He referred to some fifty or sixty petitions which had been sent to the Council from all parts of Europe, and by all kinds of people, in favour of this book, showing that the profession were by no means unanimous in condemning it. The Council would be running an enormous risk in condemning his client, for they would go counter to the feelings of, at all events, a very considerable and influential minority of the profession. He put his case, however, on higher grounds, and asked for a unanimous decision of the Council in favour of his client that this book was not an immoral one, that it was a book written with a good purpose, with a view of teaching these poor people how to avoid pain, misery, starvation, poverty, and crime. He asked the Council on that high and moral ground to come to a decision which would exonerate his client from the imputation that had been cast upon him, and would enable him to stand [illegible] eye of the world as a respected and honourable [illegible] profession which they all so much [illegible]

ACTING AS "COVER."

The consideration of Mr. Allbutt's case was suspended in order to take the case of Mr. Orme (registered as Member of the Royal College of Surgeons of England, 1865), who was summoned to appear on the following charge, as supplied by the Council's solicitor, that he, being a registered practitioner, had acted, and did act, as "cover" to one James McGowan, of No. 3, Acorn-villas, Grays, in the county of Essex, an unqualified person, in connexion with the National Medical Aid Company, Limited.

Mr. FARRER stated that he had spoken to Mr. Orme on the subject, and he was quite willing to place himself in the hands of the Council, knowing that the Council never wished to press hardly on any man. Mr. Orme stated that he was not aware of the feeling of the Council on the subject in question, and that he had erred in ignorance.

The PRESIDENT asked Mr. Orme if it was his desire to place himself in the hands of the Council.

Mr. ORME said that that was his desire.

Mr. FARRER read a letter which had been written by Mr. Orme denying that he had employed Mr. McGowan as an assistant to take a large practice in connexion with the company in question, and also a letter from Mr. McGowan stating that he had never falsely assumed the title of Doctor.

Dr. QUAIN asked what was the National Medical Aid Company, Limited.

Mr. ORME said it was a medical club for the benefit of poor people who could not afford to pay medical men their ordinary fees. They paid so much a week, as in the case of the Foresters and Oddfellows. He was paid by the society as their regular appointed medical officer, residing in the district.

Mr. TEALE: Was Mr. McGowan, before he came under your supervision, assistant to another medical man?

Mr. ORME: Yes; he was dismissed from employment, and, as I thought he was unjustly dismissed, I took him into my employ to help in a large branch practice that I was asked to take up. He came as my assistant, and, as far as I know, has never misconducted himself or attempted to call himself Doctor.

Dr. GLOVER: Is this a company or a club?

Mr. ORME: It is a company in the strict sense of the word, having a capital of £10,000, and it is registered as a company.

Dr. GLOVER: What do you do in the case of death certificates?

Mr. ORME: I always see the cases myself.

Dr. GLOVER: It might happen that a person might die without your seeing him?

Mr. ORME: It might happen. There was another medical man residing in the place who was associated with me as general medical officer; but he has now resigned, and I am the only medical officer in the district.

Dr. GLOVER: Living eighteen miles away?

Mr. ORME: Yes. I could run up by train in a short time. Neither Mr. McGowan nor myself ever attempted to infringe the laws of the Council intentionally.

Mr. MACNAMARA: I presume that there is a telegraph between you and the dispensary?

Mr. ORME: Yes, and I can get there in an hour or two.

Mr. TEALE: Did Mr. McGowan write prescriptions or dispense medicines?

Mr. ORME: He never wrote prescriptions.

Mr. TEALE: Were the medicines dispensed by him on his own individual opinion?

Mr. ORME: On his own individual opinion when I was not present.

Dr. QUAIN: By employing an unqualified person do you think you excluded or prevented a qualified person from coming to the district.

Mr. ORME: Not that I am aware of.

Dr. QUAIN: In your absence he might prescribe for cases?

Mr. ORME: Certainly he might. I am not aware of his ever having written a prescription.

Dr. MATTHEWS DUNCAN: Were you aware of the action of the General Medical Council against unqualified assistants?

Mr. ORME: I certainly was not.

Dr. MATTHEWS DUNCAN: What medical journal do you generally read?

Mr. ORME: I generally take in THE LANCET, but I have not done so for some two years past.

Dr. GLOVER: How long was Mr. McGowan acting in this capacity?

Digitized by Google

Mr. ORME: Three months.

The Council then deliberated on the case in private.

On the readmission of strangers,

The PRESIDENT said: Mr. Orme, I have to read to you the resolution of this Council, after having considered your case, as you must be aware, at considerable length and with very great deliberation. The resolution to which they have been obliged to arrive at is this:—That the Council views with the gravest disapprobation the conduct of Mr. Robert Orme as admitted by him, and while dealing with the offence leniently in the special circumstances of this case, and not erasing his name from the Register, they at the same time wish him to understand that the carrying on of a branch practice under the conditions admitted by him is a serious offence in the opinion of this Council, and is also detrimental to the public welfare. That is all that I have to say on the part of the Council.

Mr. ORME said that under the circumstances he should resign his appointment in connexion with the company, as he had no desire (and never had) to infringe the rules of the Council. He should also discharge Mr. McGowan with the proper notice.

The Council then adjourned at half-past six.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

ROYAL COLLEGE OF SURGEONS MEDICAL SCHOOL.

SIR WILLIAM STOKES said that it seemed to him that there was a peculiar responsibility and importance attached to the opening of this session, as they were, so to say, entering upon a new dispensation. "The old order changeth, yielding place to new." They were now, in truth, ringing out the old system, and ringing in the new; and this process was fraught with consequences of the utmost gravity and importance, not alone to the student, but also to the College, the profession, and the public at large. Since the last inaugural address was delivered there a union had taken place between that College and the old medical corporations of Ireland. Hence the student in medicine had now to look forward not alone to sessional examinations, but also to a final one, conducted, not as heretofore by one, but by two of the medical authorities. From this union of their College with the other corporations he anticipated the best results. The want of it too long had been a source of weakness to their profession, and had kindled feelings of jealousy and distrust, keeping them divided, powerless, and weak; and although in the negotiations between the licensing bodies many feathers had been, and still were, ruffled, and the union not as comprehensive as he trusted he might live to see it, still a good beginning had been made, and he looked forward with confidence to witnessing a happy reciprocity and overlapping of their work, and an approach made to that end desired by all—unity in science of medicine. The lecturer then gave advice as to earnestness, enthusiasm, and honesty in work. One of their main ambitions should be not to be haunted in after life by the disturbing and paralysing spectres of lost opportunities. They should keep records of what they saw and what they heard, both in hospital and school. Their motto should be—"*Nulla dies sine linea.*" The lecturer then gave a brief retrospect of the chief surgical work accomplished by some of his predecessors in the surgical chair of the College, and said that in that survey he had to acknowledge with gratitude the assistance he had derived from the comprehensive history of the College by his friend and colleague, Sir Charles Cameron.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE lecturer (Rev. S. HAUGHTON) delivered an address on "The History of the Medical School of Trinity College." He said that the school under Macartney went up like a rocket and it came down like a stick. That was because it was worked on the one-man principle. The professors were asked to surrender their opinions for those of a dictator. Under such a system he said fearlessly liberty perished, and no institution, not even the British Empire, could stand. From 1858 the school had progressed with varied fortunes, and now it had attained a prosperity not only equal but surpassing the time of Macartney, because it then stood on sand, but now it stood on a rock. It did not now depend on the one-man principle, but on the ability and energy of the teachers, and it was now worthy of the distinguished College of Elizabeth. Its future would be onward and upward. Having addressed some special remarks to the students, Dr. Haughton said he had great pleasure, in the name of the professors of the school, in asking the Provost, as head of the College, to hand over these enlarged buildings to them, and wish them God-speed in the future.

ST. VINCENT'S HOSPITAL.

MR. TOBIN said: When thinking of a subject for the remarks which it was his duty to make to them that day, this sentence from Watson's well-known introductory address occurred to him—"The profession which you and I have chosen, or which circumstances have prescribed for us, is a noble profession, and worthy of the devotion of a lifetime." He would take this for his text, and, in the first place, he would briefly indicate in what the nobleness of their profession consisted; and, in the next, how they could to the best advantage devote their time to its study and its practice. He asked them to bear in mind that when one gave advice one usually did so by going back on one's own life, reviewing its mistakes and its failures, looking into the causes thereof, and then raising a voice of warning to those coming behind. If, then, he seemed to them too emphatic in condemning any practice, they should remember that his censure included himself, and that in every word of blame he made a confession and a self-reproach. He then pointed out in what respect his profession differed from others, and mentioned cases showing that there existed in the public mind the expectation of gratuitous work from them, and he said this was not a thing to be cavilled at, but to be cherished and glorified in as a splendid inheritance put together by the devotion and self-sacrifice of those who had gone before them. He then proceeded to indicate how they could, to the best advantage, pursue their studies after they had first made a careful choice of their profession, and had in some way assured themselves of their competence for such a profession as theirs, one which required the severe mental gymnastics implied by the study of medicine. He urged the necessity of toil to obtain a position in the profession, and showed that in after life how much they were likely to lament lost opportunities.

RICHMOND HOSPITAL.

DR. O'CARROLL said he would attempt to speak to them on the subject of pathology: first, because of his faith in its necessity as part of medical education; and secondly, because of his conviction that it was that branch of investigation in which the Dublin school was most signally behindhand. First, to define what he meant by pathology. Pathology signified, as they were aware, the knowledge of the circumstances attending disease, but it had come to be narrowed down to mean that science which investigates the physical basis of disease. The science of pathology was yet in its infancy. They had ventured into depths unfathomed by those who had gone before them, but the time had been too short and the number of workers too few for many large discoveries. But what pathology had achieved might be gathered from a comparison of the state of medical knowledge before its recognition as a science and since that time. Now, as in the past, the only sure basis of progress was observation, and of all the fields for observation open to them, he submitted that pathology, studying as it did all the body changes, the sum of which they named disease, claimed their first care. They could have no ideas till they came to practise for themselves how vivid would be their diagnosis when based on a sound pathological knowledge. It was the absence of such knowledge which led such a large and persistent objectivity to such ideas as "constitution," "nerves," "system," and many others which he could mention. It had again been objected that pathology lends so little aid to therapeutics. The objection was a strong one, in the present undeveloped state of pathology. It was quite true that, to a large extent, they treated symptoms rather than physical conditions. Yet a comparison of the general course of treatment in the pre-pathological era and that of to-day would, he thought, convince them that the science of therapeutics proper had gained a very great

Digitized by Google

deal from the accurate study of morbid changes. Finally, let him remind them that pathology, if as yet it had given comparatively little aid to curative medicine, formed nearly the whole groundwork of preventive medicine. Learning the causes of disease in one generation, it aims to anticipate or neutralise those causes in the next, and thus to increase, as it undoubtedly has increased already, the average of human life. A pathologist, to attain a high position and to be capable of teaching his science, must practically devote his whole time to its study. For what reward? Not for a pecuniary one, for there was no prospect of emoluments to the pathological teacher, and few of them commenced their professional career in sufficiently independent circumstances to be able to devote themselves to a study which promised no reward but fame. As a consequence, while a knowledge of pathology was urgently needed by every physician, the opportunities for acquiring that knowledge were almost completely absent.

CHILDREN'S HOSPITAL.

DR. MADDEN desired, he remarked, to show those who were to be their pupils in the hospital that they were not wholly unreasonable in suggesting another addition to the formidable list of lectures that now confronted them as medical students. Of some of these courses they might possibly be puzzled to discover the utility when once they had passed through the examination portals of the profession; but most assuredly they would then realise the fact, which was now strangely ignored by the licensing bodies, that in whatever part of the world their future practice might be, its success would be largely influenced by their competence to deal with the protean diseases peculiar to children. This essential practical knowledge of disease, whether in adult or child life, could only be acquired in one way—namely, by clinical study, the paramount importance of which was such that it would be impossible for him to exaggerate its value, or for them to devote too much time to its pursuit. No portion of their medical training, none of the multitudinous studies by which they must fit themselves for their profession, could for a moment vie with that engaging them in the hospital, to which all other branches of medical education should be made subservient. In dealing with the diseases of children, as they would have to do in their future practice, difficulties would present themselves, and complications would arise which no mere book learning could enable them to deal with fitly. In those moments of trial, when human life depended on the soundness of their judgment and the promptitude of their action, they would face the emergency calmly and act judiciously, in proportion as they would avail themselves of the special opportunities afforded them of acquiring such a store of sound clinical knowledge as would, he sincerely trusted, hereafter make them successful and justly-honoured ministers of the healing art. Medical science had become so widely extended within recent years that subdivision or specialism was essential to its successful cultivation; and this fact, which was well recognised with regard to so many other complaints, applied with special force to the diseases of childhood. In investigating these they would have to study a new semeiology, to learn a new pathology and new therapeutics. Their old means of investigating disease would here to a great degree fail them, and they would feel almost as if they had to learn their alphabet, or as if, entering a country whose inhabitants they expected to find speaking the same language and having the same manners as the people in the land they had lately left, they were to hear around them everywhere the sounds of a foreign tongue, and to observe manners and customs such as they had never seen before. Dr. Madden concluded by impressing the importance of acquiring a sound practical knowledge of the maladies of children by diligent clinical study of those living pages of disease now open to them in that hospital.

MEATH HOSPITAL.

DR. FOOT began his address by suggesting to the students, as worthy of adoption and incorporation into the essence of their daily life, the principles of earnestness, industry, and perseverance. He urged on their attention the paramount claims of opportunity. Never again would such a combination of advantages be at their command as they had now, while their attention was sharpened by curiosity, their powers of observation keen, their memories tenacious, their duties novel, and their responsibilities light. In their youth all possibilities lay, and nothing was for them as yet irrevocable. The necessity for and the best means of cultivating the faculty of observation were dwelt on, and the lives and results of the life work of Bright, Addison, and Laennec were quoted to show that the task of clinical observation must be begun early and perseveringly followed. As the ultimate end and reward to be looked forward to as compensation for their toil and self-sacrifice, he suggested that of "excellence in their profession." This would include and cover all they could possibly hope for or expect. This was the seventh time on which he had addressed them in the same strain, and in the sixteen years that had passed since he had first done so he had seen, heard, or learned nothing to shake his faith in the correctness of the principles laid down on each occasion. It was difficult to enhance with any new and memorable charm of presentment truisms now venerable from their antiquity, but the prizes of life and how they were to be attained were questions which knocked for answer at the hearts of each successive race of students. The answer was, these prizes were only to be obtained by earnestness, industry, and perseverance, dominated by a worthy aim—excellence, irrespective of pecuniary reward.

PROFESSOR VIRCHOW ON THE CASE OF THE CROWN PRINCE.

AT the meeting of the Berlin Medical Society on Nov. 16th (of which a full report is given in the *Berlin. Klin. Woch.*, No. 47, and of which the following is an abstract), Prof. Virchow asked permission to make a statement respecting his reports upon the microscopical examinations of the portions of new growth which had been removed by Sir Morell Mackenzie from the larynx of His Imperial Highness the Crown Prince. It had been publicly stated that these reports had influenced the line of treatment adopted, and as President of that Society he felt it incumbent upon him to meet the attacks which had been made upon him on this ground. It was far from his intention to discuss the case, for it would be unbecoming to do so at a time when they were all filled with anxiety and disquiet at the recent intelligence concerning it; he only desired to explain the circumstances under which his reports were made, and to place the position he held in the matter in a clear light. He had informed Drs. von Bergmann and Gerhardt of his intention, and they wished him to say that in their capacity as surgeons in charge they did not desire to make any statement at the present time, nor that any discussion should ensue upon what would be a purely personal explanation. Professor Virchow then related how on May 21st Dr. Wegner brought him a small portion of tissue which had been excised for the purpose of microscopical examination. The fragment was so small that it was entirely examined, and the report was not published simply because it dealt with so minute a portion as to be of no value. The other reports were published by command of the Crown Prince, and were known to all. This report of May 21st states that the preparation consisted of a fragment of the surface of the mucous membrane, with, at one spot, some irregular bundles of submucous tissue. In no part were there in the deeper layers of the mucosa any elements foreign to that tissue, the only abnormality being an increase of nuclei and vascular papillæ on the surface. The epithelium was much developed, and its cells contained nuclei in process of division; in some places there were nests of epithelial cells. At one spot there was marked epithelial proliferation, the cells being enlarged, cloudy, in part containing vacuoles and enclosing cells. Nothing was found inconsistent with the characters of a simple inflammatory process. After the report was sent in, Dr. Gerhardt examined the preparation with Professor Virchow, and was satisfied that the "nests" of epithelial cells were only found in the superficial layer. It is now generally admitted that these nests—which thirty years ago were held to be distinctive of cancroid—occur in the most various and benign epithelial formations. Professor Virchow then read the next report (June 9th), which has already been

Digitized by Google

published,[1] and with respect to it he pointed out that he had expressly stated that an opinion on the nature of the whole disease could not be given from an examination limited to the excised portions. He could only frame his judgment upon what he himself examined, and he could not justly have expressed the opinion that it was still possible that a cancer existed. Such a possibility was not excluded by the terms of his report, for he had expressly affirmed that he only reported upon what was sent to him. At no time was he in a position from personal observation to gain any knowledge of the condition. He had not seen His Imperial Highness since the end of the winter, and at that time he was suffering from considerable hoarseness. His third report was dated July 1st,[2] and this confirmed the previous examination—viz., that it was a simple hard wart. But the portion excised was so superficial that no further opinion could be formed as to the condition of the deeper parts. He had expressed a wish for a detailed account and drawing of the precise relative position of the four fragments, and learnt that the first portion had been removed from the left vocal cord, and the last from the posterior third of the upper surface of the same cord. As to the other two portions, the nature of the subjacent tissue made it probable that they occupied the posterior third, probably to the right of the arytenoid cartilage; so that all the growths had probably been removed from the same region. At this time they learnt from English and German journals that Sir Morell Mackenzie had placed the responsibility of the diagnosis upon himself (Professor Virchow). He had kept silent, although he could indeed say that he was often very impatient, for he well knew the actual value which the English laryngologist would place on such a diagnosis.[3] During all this time he had not spoken to Sir M. Mackenzie, nor communicated with him by letter. Then came the authoritative reports that the morbid growths had been entirely removed, and that a small swelling which occurred had receded. It was repeatedly stated that no new outgrowths appeared at the seat of operation, and that is probably so. For, as Dr. Schmidt personally assured him (Professor Virchow), the left vocal cord is now not affected by the disease, which is described in the official report as in the hypoglottic region—how far or near to the cord Professor Virchow could not say. It seems, then, there has been no recurrence *in loco*, and that the clinical course of the case also rendered it impossible that the portions he examined were portions of cancer, if such had been present. He could not enter on the general question as to the conclusions upon the nature of the disease to be drawn from the examination of excised fragments, but could only say that he has since examined many specimens of laryngeal cancer in museums, and has not found one in which there were neighbouring warty growths quite independent of the cancer. He had never expressed the opinion that no other part of the larynx would become affected, but if, after the lapse of months, there had been no appearance of disease elsewhere the prognosis would have been much more favourable than is now unhappily the case.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

A CONFERENCE was convened by the above committee at the Society of Arts on Nov. 22nd, at 4 P.M., to discuss a scheme which they had prepared to secure co-operation between the general metropolitan hospitals and provident dispensaries, and to establish more institutions of the latter class, to be supported by small periodical payments. There were present a large number of ladies and gentlemen who were representatives of metropolitan hospitals, or had publicly interested themselves in the question of supplying medical aid to the poor.

Sir SPENCER WELLS, who presided, in the course of his remarks referred to the desirability of forming some kind of union between the various hospitals and dispensaries of the metropolis. The result of the labours of the committee during the past year had been embodied in a series of resolutions which ran as follows:—

That the governing bodies of the metropolitan hospitals be requested to co-operate with provident dispensaries, recognised by the Metropolitan Provident Medical Association, on the following conditions:—That applicants for co-operation are *bond-fide* provident dispensaries for supplying medical aid to the industrial classes, and managed by a responsible committee. That such dispensaries shall in the main be conducted in conformity with the scheme of the Medical Attendance Organisation Committee. That no pecuniary liability, apart from their own normal expenditure, be incurred by the hospitals in consequence of this connexion, and that either party be at liberty to terminate the arrangement at any time, with such notice as may be agreed upon. That the objects of such co-operation shall be as follows:—

1. *Suitable Members of Provident Dispensaries to be referred to Hospitals.*—That the medical officers of these provident dispensaries be entitled to send cases to hospitals for consultative advice or treatment; and that priority be given to patients who bring a form approved by the hospitals, and issued by the Metropolitan Provident Medical Association. That the physicians or surgeons of the hospital shall be at liberty, with the patient's consent, to retain for hospital treatment any case of clinical interest thus sent to the hospital.

2. *Limitation of the Number of Out-patients.*—That the number of out-patients received each day and the hours for seeing them be limited, so that not more patients be received than can be deliberately attended by the stated officers of the hospital (and used for clinical instruction in hospitals having schools attached), and also that the present abuse of keeping patients waiting for a great part of the day be reformed. That the "casualty department" be strictly limited to accidents and street emergencies, and that only accident cases attend more than once. That in the interests of hospitals, provident dispensaries, and of the poor themselves, it is desirable that an agent, well trained, and thoroughly conversant with the locality, rates of wages, &c., be employed at general hospitals and free dispensaries to fulfil the following duties:—(*a*) To ascertain whether the patients should receive advice and treatment gratuitously; (*b*) to make inquiries and investigation on the plan now in force at the "London" Hospital.

3. *Ineligible Applicants for Medical Relief at Hospitals to be referred to Provident Dispensaries.*—That the committees of hospitals, in co-operation with provident dispensaries, be asked to recommend to applicants for out-patients' treatment, who are *primâ facie* able to make the necessary provident payments, that they should become members of the dispensaries, with the assurance that if they should need special or hospital treatment, they would be recommended by the medical officers of the dispensaries to the hospitals for that purpose, and be received by them. That notices, giving particulars of the provident dispensaries in co-operation with the hospitals, be placed in their out-patients' waiting rooms. That this proposal be adopted, on the understanding that all patients, whose cases are *primâ facie* urgent, are eligible for first treatment, and also that those cases which are vouched for by the physicians or surgeons as of special interest be retained for hospital treatment.

4. *Students to be permitted to make use of Provident Dispensaries for the Study of Common Diseases.*—That students of hospitals be permitted, under suitable regulations, to attend the practice of provident dispensaries in co-operation with their hospitals, when the medical officers see or visit their patients.

He invited those present to join in the discussion on the plan, and for the convenience of the meeting resolutions would be proposed, which could be discussed in detail.

Mr. W. BOUSFIELD moved: "That the scheme of the Medical Attendance Organisation Committee for co-operation between hospitals and provident dispensaries be accepted as a basis of negotiation." He said that at the hospitals many were treated who could afford to pay, and the out-patient departments were for the most part overcrowded and needed reforming. The Metropolitan Provident Association, which was formed in 1881, had been appreciated by the poor, but its progress had been slow from two causes: general practitioners had not supported it on the ground that people who could afford to pay were admitted as patients, and because no check had been put on the number of out-patients admitted to hospitals. Under the new scheme minor ailments would be treated at dispensaries, and, should need for consultative opinion arise, they could be transferred to the hospital.

Dr. GILBART SMITH, in seconding the motion, thought that the scheme would neither harm the hospitals nor deprive the really necessitous and deserving poor of the means of relief which were now open to them.

The Rev. Dr. WACE (King's College) proposed as a modification of the resolution, "That the scheme of the Medical Attendance Organisation Committee for co-operation between hospitals and provident dispensaries be referred to a committee composed of hospital representatives and of members of the Medical Attendance Organisation Committee for their consideration, and that the committee be requested to bring the scheme, when settled by them, before the governing bodies of their respective hospitals." This was seconded by Mr. Holmes.

After further discussion, in which Dr. Alfred Carpenter, Colonel Francis Haygarth, Mr. Jabez Hogg, the Hon. Conrad

[1] See THE LANCET, vol. i. 1887, p. 1302. [2] Ibid., vol. ii. 1887, p. 133.
[3] Vide Morell Mackenzie: Growths in the Larynx, p. 36. (London, 1871):—"*Malignant growths:* It is not always easy to distinguish between benign and malignant laryngeal growths; the latter, however, are diagnosed by being thoroughly blended with the surrounding tissue, by being very frequently ulcerated, and by the constitutional history and symptoms of the patient. In these cases, should particles be expectorated or removed during life, with the aid of the laryngoscope, *the microscope cannot be relied on for differential diagnosis.* Several cases have come under my notice where the histological features were decidedly those of cancer, whilst the clinical history was of a totally opposite character, and *vice versâ*."

Digitized by Google

Dillon, and Colonel Montefiore joined, the amended resolution of Dr. Wace was put as the substantive motion, and carried unanimously.

Up to the time of the meeting representatives had been appointed by St. George's, St. Mary's, Middlesex, Great Northern Central, Evelina, and King's College Hospitals.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5704 births and 3747 deaths were registered during the week ending November 19th. The annual rate of mortality in these towns, which had been 21·5, 21·4, and 20·0 per 1000 in the preceding three weeks, rose again last week to 21·1. During the first seven weeks of the current quarter the death-rate in these towns averaged 19·9 per 1000, and was 1·0 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·5 in Hull, 15·3 in Leicester, 15·5 in Wolverhampton, and 16·3 in Brighton. The rates in the other towns ranged upwards to 29·0 in Halifax, 29·3 in Bolton, 29·6 in Preston, and 30·4 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 466 and 402 in the preceding two weeks, were last week 404; they included 85 from scarlet fever, 84 from measles, 80 from whooping-cough, 61 from "fever" (principally enteric), 38 from diphtheria, 31 from diarrhœa, and 25 from small-pox. These zymotic diseases caused the lowest death-rates last week in Bristol and Wolverhampton, and the highest rates in Blackburn, Bolton, and Sheffield. The greatest mortality from scarlet fever occurred in Oldham, Birkenhead, and Blackburn; from measles in Cardiff, Bolton, Bradford, and Derby; from "fever" in Leeds, Derby, and Bolton. The 38 deaths from diphtheria in the twenty-eight towns included 25 in London, 4 in Huddersfield, 2 in Brighton, 2 in Manchester, and 2 in Salford. Small-pox caused 25 deaths in Sheffield, but not one in London or in any of the twenty-six other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 16 patients on Saturday last, showing a further slight increase upon recent weekly numbers. The number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital at the end of the week was 2888, showing a further increase upon the numbers on previous Saturdays, although the number of admissions showed a further decline. The deaths referred to diseases of the respiratory organs in London, which had been 506 and 438 in the preceding two weeks, rose again last week to 461, and exceeded the corrected average by 40. The causes of 66, or 1·8 per cent., of the 3747 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·6, 20·6, and 19·9 per 1000 in the preceding three weeks, rose again to 22·0 in the week ending Nov. 19th; this rate was 0·9 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 17·3 and 18·8 in Leith and Paisley, to 23·9 in Glasgow and 24·4 in Aberdeen. The 549 deaths in the eight towns last week showed an increase of 51 upon the numbers returned in the previous week, and included 26 which were referred to whooping-cough, 16 to scarlet fever, 11 to "fever" (typhus, enteric, or simple), 8 to measles, 7 to diphtheria, 6 to diarrhœa, and not one to small-pox; in all, 74 deaths resulted from these principal zymotic diseases, corresponding with the number in the preceding week. These 74 deaths were equal to an annual rate of 3·0 per 1000, which exceeded by 0·7 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 26 in each of the preceding three weeks, were again 26 last week, of which 14 occurred in Glasgow, 5 in Dundee, 3 in Edinburgh, and 3 in Greenock. The deaths from scarlet fever were 16 last week, against 19, 14, and 17 in the preceding three weeks; they included 10 in Dundee and 2 in Glasgow. The deaths referred to "fever," which had been 6 in each of the preceding four weeks, rose last week to 11, of which 5 were returned in Edinburgh, 4 in Glasgow, and 2 in Aberdeen. The 8 fatal cases of measles showed a further increase upon the numbers in recent weeks, and included 3 in Edinburgh, 2 in Glasgow, and 2 in Perth. Four of the seven deaths from measles (showing a decline of 3 from the number in the previous week) were returned in Glasgow. The 6 deaths attributed to diarrhœa showed a further decline from the numbers in recent weeks. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 131 and 107 in the preceding two weeks, rose last week to 144, and were 7 above the number returned in the corresponding week of last year. The causes of 73, or more than 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 31·0 and 32·1 per 1000 in the preceding two weeks, further rose to 34·6 in the week ending November 19th. During the first seven weeks of the current quarter the death-rate in the city averaged 29·3 per 1000, the mean rate during the same period being but 19·2 in London and 18·5 in Edinburgh. The 234 deaths in Dublin last week showed a further increase of 17 upon the numbers in recent weeks; they included 8 which were referred to scarlet fever, 6 to diarrhœa, 5 to measles, 4 to "fever," 3 to whooping-cough, 3 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 42, 41, and 45 in the preceding three weeks, declined last week to 29; they were equal to an annual rate of 4·3 per 1000, the rate from the same diseases being 2·2 in London and 3·0 in Edinburgh. The fatal cases of scarlet fever, measles, and whooping-cough showed a considerable decline from the numbers in recent weeks; the deaths from diarrhœa corresponded with the number in the previous week, and those from "fever" showed an increase of 1. Two inquest cases and 2 deaths from violence were registered within the city; and 55, or nearly a fourth, of the deaths occurred in public institutions. The causes of 38, or more than 16 per cent., of the deaths in the week were not certified.

THE SERVICES.

Deputy Surgeon-General G. M. Slaughter has taken over the duties of Principal Medical Officer of the Chatham District, in room of Deputy Surgeon-General E. H. Roberts, who proceeds to India.

Deputy Surgeon-General W. Colles has handed over his charge at Peshawur, and has joined at Meerut.

Surgeon-General W. A. Mackinnon, C.B., from head-quarters, will replace Sir J. A. Hanbury, K.C.B., as Principal Medical Officer at Gibraltar, who goes to India.

WAR OFFICE.—Brigade of Foot Guards: Surgeon-Major William Ralph Lane, Scots Guards, to be Brigade Surgeon, vice A. G. Elkington, Grenadier Guards, retired (dated Nov. 5th, 1887).

ADMIRALTY.—The following appointments have been made: Surgeon J. R. Dow, to the *Cordelia;* Surgeon J. S. Hughes to the *Himalaya* (dated Nov. 17th 1887).

ENGINEER VOLUNTEERS.—2nd Gloucestershire (the Bristol): Acting Surgeon G. M. Smith resigns his appointment (dated Nov. 19th, 1887).

RIFLE VOLUNTEERS.—2nd Bucks (Eton College): Surgeon J. W. Gooch resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement (dated 19th November, 1887).—1st Edinburgh (the Queen's City of Edinburgh Rifle Volunteer Brigade): Surgeon and Honorary Surgeon-Major R. J. B. Cunynghame resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement (dated 19th November, 1887).—1st Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Arthur Ernest Marsack, Gent., to be Acting Surgeon (dated Aug. 13th, 1887).—13th Middlesex (Queen's Westminster): Acting Surgeon W. H. Fenton-Jones resigns.

Digitized by Google

his appointment (dated Nov. 19th, 1887).—14th Middlesex (Inns of Court): The undermentioned officer resigns his commission:—Surgeon J. H. Morgan (dated Nov. 19th, 1887). 18th Middlesex: Druce John Slater, M.B., to be Acting Surgeon (dated Nov. 19th, 1887).

Correspondence.

"Audi alteram partem."

THE NATURE OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—Sir James Paget, in the Morton Lecture, says: "We cannot tell why small-pox is especially manifested on the skin." In the nomenclature, small-pox, having fallen amongst the "specific febrile diseases," is regarded as a typical blood disorder. Believing that the fermentation theory has misled us, I hold this an unfortunate association, and would group small-pox with "parasitic diseases of the skin." The manifestations of small-pox can be accounted for by an hypothesis that spores dispersed from a small-pox victim, falling on "good ground," vegetate locally; that the local lesion and constitutional disturbance are sequences of that local growth. In ringworm spores may be carried by the air and settle on the skin. "In the first place the fungus takes root in the superficial epidermic layers." "The fungus elements act as a foreign body, irritating the subjacent papillæ." These become hyperæmic. Serous exudation follows, the epidermis is loosened and raised into vesicles, the part grown on is then protected from further vesicular eruption (see Hebra, new series, vol. v., p, 215). "Fever may also accompany such an eruption if it is spread over a large part of the trunk" (p. 201). There is no doubt that small-pox is propagated by spores (see Dr. Buist's "Vaccinia and Variola"). It is probable that they are given off in enormous numbers from a small-pox patient. An unprotected person entering a spore-laden atmosphere would arrest some of them. If each spore produced a pock at the spot where it was arrested, we would expect the pocks to be most numerous on well-aired parts, the respiratory tract, face, and hands; less so in parts covered by clothes and hair; least on unaired surfaces, such as the œsophagus, vagina, and urethra. It is so in small-pox, with the exception of the conjunctiva (the spores were washed away to the eyelashes). If we imagine the spores to be blood-carried, we cannot explain the distribution of pocks. The other theory does account for it. On the fermentation hypothesis the number of pocks would be independent of the number of spores originally leavening the blood. But on the unprotected the number of pocks does depend on the circumstances of exposure. Such a person passing a small-pox patient in the street would have discrete small-pox. Such a person attending a small-pox patient in a room for days, or sleeping in the same bed, would have confluent small-pox. The instances of most extensive confluent eruption over the body in my experience have been personal attendants on small-pox patients admitted into general hospitals. The longer such a one is exposed to infection, the nearer to the source, the fewer intervening obstacles and the more confined the space, the greater will be the number of spores adhering, the greater the number of pocks.

I am, Sirs, yours truly,

Hospital Ships, Nov. 20th, 1887. R. A. BIRDWOOD.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—I have read with great interest the many letters which have appeared in the late numbers of THE LANCET on the subject of cancer, and also the admirable lecture in last week's number by Sir James Paget, Bart., who is decidedly of opinion that the disease is not contagious. Now, with your kind permission, I should like to bring before the profession a few cases which have happened in my own practice, and which can hardly, I think, be explained upon any other hypothesis than that of contagion.

1. Some years ago a gentleman, who had spent many years in India, came under my care for cancer of the lip, for which he refused to submit to any operation. When he was confined to his bed a favourite little terrier was scarcely ever out of his room, and, as is the habit of such little dogs, frequently licked his master's lips. This dog died, before his master, of cancer of the tongue.

2. A lady suffering from cancer of the uterus and vagina was nursed by a strong, healthy young woman of nineteen. She, in spite of my remonstrances, persisted in washing the rags which were saturated with the discharges from her mistress's wounds. Six months after the death of the lady this young woman was admitted into the North Devon Infirmary with a large mass of cancer in the axilla, and speedily died of the disease.

3. Since I have been in practice in this small town five surgeons, all of whom had officiated at the North Devon Infirmary, have died of cancer. Such a mortality can hardly be conceived except on the supposition that the disease was communicated, at least to some of them, during their manipulations on patients suffering from cancer.

I am, Sirs, yours faithfully,

Barnstaple, Nov. 21st, 1887. RICHARD BUDD, M.D., F.R.C.P.

To the Editors of THE LANCET.

SIRS,—The letter in your last issue under the above heading recalls to my mind the case of a man who died in the Liverpool Royal Infirmary in 1884 from cancer of the penis and secondary glandular disease, his wife having previously succumbed to malignant disease of the uterus. Like Mr. Whitehead's case, this may have been purely coincidental, but may also possibly bear another interpretation.

I am, Sirs, yours truly,

ARTHUR H. CLEMOW, M.D.

Earl's-court-square, S.W., Nov. 21st, 1887.

MANCHESTER.

(*From our own Correspondent.*)

VICTORIA UNIVERSITY.

THE ceremony of conferring degrees took place in the Town Hall, in the presence of a large and fashionable audience. Thirty-one degrees in all were conferred, in Arts, Science, and Medicine. The Vice-Chancellor, in his report, stated that the number of candidates at the various examinations was increasing yearly, amounting in the past year to 285. At a meeting of the University Court held the same day an important step was taken in the admission of the Yorkshire College at Leeds as a college of the University. The application was strongly supported by the Marquis of Ripon; and the Duke of Devonshire, Chancellor of the University, also wrote, expressing his sympathy with the application. After considerable discussion, it was unanimously decided to admit the Yorkshire College. Thus, another provincial medical school will have it in its power to offer a degree to its students. It is, however, to be hoped that, for the credit of the Leeds medical students, we shall not hear again of such a silly public demonstration as was made last week in the streets of Leeds by some of their number because they had been invited to attend a meeting under the auspices of the Young Men's Christian Association.

INFIRMARY AND SOUTHERN HOSPITAL.

The offer, alluded to in these columns, to build and equip a cottage hospital in Hulme, to be handed over to the Royal Infirmary, has been reluctantly declined by the board of that charity, as involving pecuniary responsibilities they do not see their way clear to incur. The recent death of Madame "Jenny Lind" has served to remind the present generation of the debt of gratitude owing to her for the substantial assistance given by her in building the third wing to the infirmary. During the past year the Southern Hospital has extended its sphere of operations by opening a lying-in department, and Dr. Sinclair, in the report presented at the annual meeting, was able to state that the public had responded well to the application for increased support to meet the additional expenses thus incurred. Good and useful work is being done by this hospital. At the last meeting of the Medical Society (which, by the way, continues this year to hold some of its meetings at the

Digitized by Google

Literary and Philosophical Society's rooms, George-street) Dr. Sinclair read a paper on some cases of extirpation of the uterus for malignant disease.

OWENS COLLEGE.

We have had some distinguished visitors at the College lately, the latest being Earl Granville and the Lord Mayor of London, who, during a short visit paid to the city for the purpose of seeing the Jubilee Exhibition, took the opportunity of going through the laboratories, class rooms, and various departments of the College. The Combe lectures on Physiology are being continued at the College this winter by Professor Stirling, and are attracting large audiences.

BANQUET TO THE CHAIRMAN OF THE HEALTH COMMITTEE.

On Friday evening a complimentary dinner was given at the Grand Hotel to Mr. Alderman Schofield, J.P., chairman of the Manchester Health Committee, as an expression of appreciation by his fellow-citizens of his work in the cause of sanitary progress during the last eighteen years, and of sympathy with him in the vexatious and uncalled-for litigation to which the Health Committee was exposed a few months ago. The dinner was largely attended by leading citizens, members of the Corporation and the medical profession, and all the speakers bore testimony to the sterling honesty, integrity, and devotion to his committee's work so long shown by Mr. Schofield.

VACCINATION CORRESPONDENCE.

Our daily press has not escaped the outbreak of correspondence *re* compulsory vaccination lately engaging attention both in your columns and those of other London papers. Amongst the facts and arguments brought forward showing the protection afforded by properly performed vaccination, none were more striking or convincing, except to those who will not be convinced, than some adduced from the experience of the Infirmary Small-pox Hospital by Dr. Tomkins, formerly medical superintendent there.

November 21st.

LIVERPOOL.

(From our own Correspondent.)

THE MAYOR AND THE HOSPITALS.

FOLLOWING the example of his predecessors in office, the newly elected Mayor (Mr. Oakshott) visited the Infirmary for Children on the Sunday following his election, and last Sunday attended St. Barnabas Church in state, when a sermon was preached by the Rev. Canon Eyre, vicar of St. Helen's. The collection on behalf of the Royal Southern Hospital amounted to £110, exclusive of the donation of £25. After the service the Mayor visited the hospital. His worship also attended the first meeting of the Hospital Sunday Committee on the 17th inst., and took the chair.

DEATH OF A SHIP CAPTAIN FROM LAUDANUM.

An inquest was recently held by the city coroner on the body of a German ship captain, who had died shortly before reaching port. A post-mortem examination was made by Dr. Barron, who found indications of opium poisoning, as well as of recent intemperance. He removed the stomach and contents, and these were subsequently examined by Mr. Edward Davies, analytical chemist, who found distinct traces of morphia, and also obtained a spirituous extract giving the odour of opium extremely well marked, but there was no trace of meconic acid. It appeared from the evidence of the chief and second mates that the deceased had been for some time addicted to intemperance. In consequence of this, which led to the ship being placed in imminent danger, all intoxicants were kept out of his way. He contrived, however, to get hold of a large bottle of laudanum, a considerable quantity of which he evidently drank. An open verdict was returned. This case shows the importance of temperance being practised in the cabin even more than in the forecastle of all ships.

THE ASSIZES.

Since the 11th inst. Mr. Justice Day has been presiding in the Crown Court trying prisoners, of which there has been a very large number awaiting trial. Among these was a woman of loose character, indicted for the manslaughter of her paramour by throwing a lighted paraffin lamp at him, causing injuries from which he died. There was also a chemist charged with a series of indecent assaults on female children, the assaults having been committed in an apartment adjoining his shop. He appeared to have been in the habit of enticing the children in by offers of sweetmeats. The judge described the case as the worst of the kind he had ever tried, and regretted that, as the jury, acting under his direction, could only convict him of an attempt, instead of the full charge, the utmost punishment which could be inflicted was two years' hard labour, to which he sentenced him. There are still many serious cases to be tried.

THE HOSPITAL FOR WOMEN.

Among the other patients in the Hospital for Women, there is, under the care of Dr. Briggs, a Spanish woman, aged thirty-six, the subject of a protracted labour completed by instruments; this occurred in Spain seven years ago. Since then she has suffered from an unusually large vesico-vaginal fistula and deeply torn perineum, the bladder, vagina, and rectum forming one common cloaca. On admission the bladder was found to be turned inside out, so that the mucous membrane of the fundus vesicæ was protruded through the vulva like a hernia. After a fortnight's rest in bed the bladder had almost receded into the pelvis. The whole vesical floor was apparently absent. By making independent vesical and vaginal flaps on each side the gap was filled in without leaving tension on the sutured edges. The repair has been successful.

THE REMARKABLE CASE OF EXTRA-UTERINE GESTATION.

The case described in a previous letter has terminated most favourably, the patient being now, on the forty-second day, practically convalescent. She is sitting up daily, the original sac is represented by a mere sinus, and both temperature and pulse are normal.

Liverpool, Nov. 22nd.

EDINBURGH.

(From our own Correspondent.)

THE UNIVERSITY COURT.

AT its last meeting the Court adopted a minute expressing its regret at the retirement of Mr. Campbell Swinton, who has for the last forty years acted as one of its members in one or other representative capacity. The minute recognises that to his influence and the wise counsel he has advocated has been largely due the prosperity that has so signally marked the period of his tenure of office, and closes with a sympathetic expression of regard and good wishes on behalf of the remaining members. The report of the Business Committee of the University General Council, advocating measures of reform referred to in a recent letter, was brought up for consideration, but it was decided that the subject should be fully considered in all its bearings at a special meeting when a Bill on the subject should again be submitted to Parliament.

PROSPECTIVE CHANGES IN THE MEDICAL CURRICULUM.

During last summer the subject of an alteration in the curriculum that should make their labours, if not lighter, yet more evenly distributed over their period of study, and increase their opportunities of clinical instruction, was under discussion among the students; and their representative council drew up for presentation to the Senatus Academicus a series of propositions which it was thought would attain these ends if adopted. In effect, the students prayed for a redistribution of the professional examinations, by which the first and intermediate examinations should be placed anteriorly to the position they have till now occupied in the curriculum, and that an arrangement should be made by which they may be completed by the end of the second *annus medicus*, thus leaving two years and a half free for the clinical subjects, along with Pathology and Materia Medica. These proposals have now been considered by the Senatus, and in part adopted. It is to be in due time enacted that a student may pass the first professional examination in two sections within the first year of study; and it is anticipated that a similar enactment will be made by which he may pass in Anatomy and Physiology at the end of the second year. In regard to the latter point there is said to be a little difficulty; but there is no doubt that what opposition may arise to it will be of a formal nature,

Digitized by Google

and will be easily overruled in accordance with the wide consensus of opinion in favour of the proposed alteration. Thus the last two years and a half of the student's undergraduate life will be freed from the incubus of impending examinations in subjects not directly bearing on his clinical work, an arrangement by which he can scarcely fail to profit as regards his preparation for the practical duties of his profession. The Senatus cannot be too highly commended for the wisdom and foresight evinced in their adoption of these suggestions, which will do much to enhance the value of the curriculum as a whole, and in large measure remove the one drawback it has laboured under—viz., the relatively larger development of its theoretical at the expense of its clinical aspect.

THE ETIOLOGY OF TUMOURS.

A special meeting of the Medico-Chirurgical Society was held last week for the discussion of the question of the origin of tumours. The subject was introduced in a paper by Dr. G. Sims Woodhead, which evoked a good deal of criticism, both favourable and adverse. His view is based on a study of the behaviour of the layers of the blastoderm in early stages of its development, and upon the observed inter-relation of the structures derived from each at different stages of adult life. He assumes a certain amount of antagonistic action between the developed derivative tissues from each layer in respect to functional and vegetative activity; and, by tracing the typical life history of each group, shows that their period of vital apogee and retrogression are not contemporaneous, but that at one stage the likelihood of invasion is greater on the one hand, at another period on the other. Thus in youth the connective tissue type of tumours preponderates; in middle life the histioid; and in old age the epithelial. In each case an irritant, in the wide sense of the term, must be supposed to determine the locality of tumour manifestation, whether the irritant be a trauma, an organised particle, or due to an hereditary local weakness. Further, an hereditary tendency to the production of one or other type of tumour may be established, depending on the age of the parents of the individual, and the state of their tissue equilibrium, as above defined, at the time of the individual's development; and such a tendency may become exaggerated in the course of successive generations till it becomes a diathesis and tumour formation actually occurs. The above is an outline of the argument adopted, which was largely amplified in the paper, and illustrated in many of its chief points by the citation of cases and the exhibition of specimens. In the discussion that followed, Professor John Chiene stated his opinion, based on a large series of cases tabulated for the purpose, that the great majority of malignant tumours occurred in consequence of local injury, giving "injury" the broad meaning of a local irritant or depressant. Dr. James referred at length to the biological aspects of the question; while Dr. Duncan expressed the opinion that malignant tumours are due to the action of micro-organisms. Dr. Joseph Bell, Dr. Russell, Dr. Macgillivray, and other gentlemen also took part in the discussion.

Edinburgh, Nov. 22nd.

ABERDEEN.

(From our own Correspondent.)

THE MEDICO-CHIRURGICAL SOCIETY.

THE annual meeting of the Aberdeen Medico-Chirurgical Society was held on Thursday, the 17th inst., when the following office-bearers were elected for the year:—President, Dr. James Rodger: Vice-President, Dr. Smith-Shand; Secretary, Dr. Edmond; Recording Secretary, Dr. MacGregor; Treasurer, Dr. Gordon; Librarian, Dr. McKenzie Booth; Council—Drs. Jackson, Ogilvie Will, Urquhart, Garden, and McKenzie Booth. The following gentlemen were also appointed representatives to the North of Scotland Medical Association—viz., Drs. Rodger and Edmond *ex-officiis*, and Drs. McWilliam and Theodore Thomson elected.

MEDICAL STUDENTS' SOCIETY.

As a result of some remarks made by Professor M'William in his introductory lecture at the opening of the winter session, the old Medical Students' Debating Society, which ceased to exist in 1880, has been resuscitated, and its first meeting was held on the evening of Friday, the 18th inst. Professor M'William delivered the inaugural lecture, choosing for his subject "Thought-reading." At the close of the meeting the following office-bearers were elected:—Honorary Presidents: Professors Struthers and M'William. Hon. Vice-Presidents: The other members of the Medical Faculty and the infirmary staff. President: Mr. Arthur Keith. Secretary: Mr. Park. Treasurer: Mr. M'Kay. Two gentlemen from each of the four years were appointed members of the committee.

FEVER AT MONTROSE.

The village of Ferryden, Montrose, is again the victim of a fever epidemic. During the last few weeks there have been between fifty and sixty cases of scarlet fever in the village, with four certified deaths, and two others which may, it is feared, be attributed to the same cause.

Aberdeen, Nov. 23rd.

DUBLIN.

(From our own Correspondent.)

QUEEN'S COLLEGE, GALWAY.

THE chair of Surgery in this institution is now vacant in consequence of the death of Dr. J. Valentine Browne, and the appointment, which is in the gift of his Excellency the Lord-Lieutenant, will be filled up some time in December, The gentleman selected will hold office for seven years only, and will enter upon his duties on January 9th, 1888.

FRACTURE OF THE SACRUM.

Fractures of this bone are so very uncommon that brief details of a case at present in the Meath Hospital may be of interest. A policeman, aged forty-six years, on the 17th inst. fell from a ladder a height of between twenty-five and thirty feet, the ladder falling under him at the time of the accident. On removal to hospital there was found a deep indenture corresponding to the middle third of the sacrum, and also a slight wound. He has been unable to pass urine since his admission, a catheter being used every four hours. A padded pelvis band has been applied, and the wound treated antiseptically. The lower fragment, it may be mentioned, was more prominent than the upper, and a finger can be introduced between them. The pulse was 104 on admission, and the temperature normal; but the latter on the 21st inst. went up to 102°, and to-day (Tuesday) it was 100°. I believe this is the ninth case recorded from other causes than gunshot injury.

ROTUNDO LYING-IN HOSPITAL.

At a meeting of the Dublin Town Council last Monday, the report of the Committee on the City Hospitals was under consideration. The grant to the Rotundo Lying-in Hospital—one of the largest institutions of the kind in Europe, having a world-wide fame, and admirably managed—has this year been suspended. The reason stated by the Nationalist members of the Town Council, who are in a large majority, for this procedure, is because they consider there are not a sufficient number of gentlemen belonging to their own religious persuasion on the board of governors of the hospital. As one of the Corporation, Sir George Moyers pointed out that what they had to consider was the treatment the patients received in the Rotundo Hospital, and not to deal with the religion of the governors.

THE PERMANENCY OF RETIRING ALLOWANCES TO MEDICAL MEN.

The guardians of the Limerick Union some time since passed a resolution granting Mr. Going, late medical officer of Coolycasey dispensary district, a superannuation allowance of £75 per annum. But they soon repented of their generosity—for what reason is unknown,—and notice of motion was given for the purpose of rescinding the arrangement entered into. Fortunately for Mr. Going, the Local Government Board have very properly interfered, and last week informed the guardians that the Union Officers' Superannuation Act contained no provision enabling guardians to revoke any grant of a superannuation allowance duly made by them in pursuance of the statute.

Dublin, Nov. 22nd.

AN extensive epidemic of measles prevails in the villages of Boughton and Dunkirk, in East Kent. In the last-named village the schools have had to be closed.

PARIS.

(From our Paris Correspondent.)

CANCER OF THE LARYNX.

M. TILLAUX showed a patient at the Academy of Medicine upon whom he had performed tracheotomy five months ago for the relief of suffocation due to cancer of the larynx. Since then there has been, as is generally the case soon after an operation of the kind, a partial retrogression of the tumour, and the patient has resumed his occupation, having recovered his appetite, strength, and spirits, and gained seven pounds in weight. M. Tillaux said he made this communication because the question as to the best line of conduct in such cases is still open, as is shown by M. Schwartz in his thesis on the subject. Should a radical cure be attempted by extirpation of the larynx, or should the palliative operation of tracheotomy be adopted? M. Tillaux said that he thought the history of his case showed that tracheotomy was useful in some cases, and for his part he was not disinclined to prefer it, as a rule, to extirpation. Professor Verneuil considered that the superiority of tracheotomy over extirpation was incontestable. With the latter operation, when the patient does not die from the immediate consequences, he speedily succumbs to a relapse. In one case of epithelioma, tracheotomised by M. Verneuil a year ago, the tumour was so considerable that it was difficult to understand how it was possible to breathe at all. After tracheotomy, or rather Krishaber's operation of laryngo-crico-tracheotomy, the patient resumed his ordinary business, and is even able to speak pretty distinctly when the opening of the cannula is occluded. M. Richet mentioned a similar case. M. Labbé did not agree with his colleagues. He said that he had, like them, performed tracheotomy for the relief of laryngeal cancer, and should no doubt do so again. But he could not admit this to be the only operation possible, and that there are not cases in which we ought to practise extirpation of the larynx. As a rule, extirpation is done too late, upon subjects already tracheotomised, and for the relief of aggravated symptoms. It is reasonable to suppose that better results would be obtained if the operation were performed as soon as the cancerous nature of the growth is recognised, and before there is any secondary infection of the neighbouring glands. The gravity of the operation is not so considerable as is generally supposed. In four cases of the kind M. Labbé had had three absolute operative successes, the patients living for different lengths of time without relapse. In the fourth case death was due to the accidental negligence of the nurse, who omitted to change the cannula, as had been directed; in consequence the patient was nearly asphyxiated by the accumulated secretions, and died a fortnight later of septic pneumonia. The thesis of M. Schwartz ("Thèse d'Agrégation," 1886), the most impartial monograph upon extirpation of the larynx in the French language, necessarily serves as a groundwork for all general reviews of this question, and the current number of the *Bulletin Médical* contains a good *résumé* of of it by M. Maurice Hache, who brings the statistics of M. Schwartz up to date by the addition of recent cases. In 105 observations quoted of total extirpation of the larynx, death took place fifteen times within the first week from hæmorrhage, collapse, embolism or septicæmia, or other causes; twenty times during the second week from pneumonia or broncho-pneumonia. To these are added one case of death from pulmonary gangrene on the twenty-fifth day, five of late pneumonia, and two of exhaustion, making forty-three deaths in all from the operation itself, a mortality of 40 per cent. Twenty-eight of the remaining relapsed, two before the expiration of three months, six others before six months, eight before a year, two between the first and second years, and two before two years and a half. Thirty-four patients are recorded as cured—fifteen after six months' observation, eight more after less than a year. One was published fifteen months; one, sixteen months; two, from two to three years; three, from three to four years; two, five years; and one, ten years after operation. Counting those as cured who have lived two years, there have been eight certain successes in 105 cases. Of twenty-seven published cases of partial extirpation, in one there had been no relapse after eighteen months, in another the cure was definite after seven years. Seven other operations had been successful, but the time elapsed at the date of publication was under a year and a half. From a functional point of view the condition of those who have been operated on is less unsatisfactory than might be supposed. Deglutition is restored sometimes within a week, nearly always after a couple of months. And by means of Güssenbauer's artificial larynx there is a very fair restoration of the voice.

NEW TREATMENT OF PHTHISIS.

The report of the Commission appointed by the Academy to study the effects of hydrofluoric acid in phthisis has just been published. It begins by stating that glass workers attribute a curative action to the vapours, a fact pointed out twenty-five years ago by M. Didierjean, and which led to experimentation with this agent in the Paris hospitals. The results on the whole were negative, although it was thought likely that hydrofluoric acid might prove useful in diphtheria. The question has been reopened recently by MM. Seiler and Garcia (see THE LANCET, Oct. 15th), who now claim for hydrofluoric acid a foremost place in pulmonary therapeutics. The Academy Commission, MM. Herard, Féréol, and Proust, point out that the acid is highly antiseptic, ranking with biniodide of mercury in this respect. A solution of $\frac{1}{1000}$ to $\frac{1}{500}$ cleanses fetid wounds. It has a considerable anti-bacillary power, which the Commission has tested in guinea-pigs and rabbits infected by the inhalation of pulverised sputum. As regards the statements made by MM. Seiler and Garcia, the Commission thinks that, taken in their *ensemble*, they are exact, although it is somewhat premature as yet to affirm that the cures are permanent. They conclude that inhalations of hydrofluoric acid possesses an undoubted therapeutic action when phthisis is not too far advanced, and that they are both free from danger and easy of application. The *Journal de Médecine de Paris* publishes a long and interesting article by Dr. Ley on the treatment of phthisis by the inhalation of sulphurous acid. After relating numerous experiments upon the admixture of the gas with the atmosphere and the effects of inhalations of different strengths upon animals, the writer concludes that the therapeutic dose for man, is an atmosphere containing from $\frac{1}{5000}$ to $\frac{1}{10000}$ of sulphurous acid. This may be obtained by burning six grammes of sulphur for each cubic metre of room space for the first three days; after which (the walls being saturated) five grammes will suffice. The patients should not go into the rooms until ten or twelve hours after the combustion, which should always be performed in a well-aired chamber. M. Ley advises this treatment in torpid phthisis, and recognises febrile symptoms as a contra-indication.

ELECTION OF M. PÉAN.

The Academy has at length admitted M. Péan to its number, electing him to the membership last Tuesday by forty-seven votes, against thirty-four given to M. Le Dentu. M. Péan is perhaps better known than any other surgeon in the Academy, and it is difficult to understand why that venerable institution should have hitherto refused him a representative seat.

Paris, Nov. 23rd.

Medical News.

UNIVERSITY OF LONDON.—The following gentlemen have passed the recent M.B. examination:—

FIRST DIVISION.

Balgernie, Wilfred, St. Bartholomew's Hospital.
Barendt, Frank Hugh, Liverpool Royal Infirmary.
Barwise, Sidney, Queen's and Mason Colleges, Birmingham.
Braddon, William Leonard, Guy's Hospital.
Brook, W. Henry Breffit, St. Bartholomew's Hospital.
Brown, Herbert Henry, University College.
Caldecott, Charles, Guy's Hospital.
Calvert, John Telfer, St. Thomas's Hospital.
Clarke, William Frederick, Guy's Hospital.
Deanesly, Edward, B.Sc., University College.
Featherstone, W. Barltrop, Queen's College, Birmingham.
Finley, F. Gault, McGill University, Lond. Hosp., and Vienna.
Flemming, Percy, University College.
Gee, Frederick W., University College.
Gill, Ralnsford Foster, University College.
Godfrey, Albert E., Northampton General Infirmary and St. Thomas's Hospital.
Holder, Sidney Ernest, University College.
Jecks, Cyril William, University College.
Kelsall, Henry Truman, London Hospital.
Kidd, Hugh Cameron, St. Thomas's Hospital.
Lawrence, T. W. Pelham, University College.

Digitized by Google

Lys, Henry Grabham, London Hospital.
Marriott, Hyde, B.Sc., University College.
Moynihan, Berkeley G. Andrew, Yorkshire College.
Nevins, J. B., Liverpool School of Medicine and Guy's Hospital.
Rennie, George E., B.A., Sydney, University College.
Risdon, William Newt, Guy's Hospital.
Routh, Charles Frederic, Guy's Hospital.
Smith, Hugh, London Hospital.
Solly, Ernest, St. Thomas's Hospital.
Stedman, Frederic Osmund, Charing-cross Hospital.
Sunder, Charles Edward, University College.
Taylor, Frederick Howard, London Hospital.
Thane, Edgar Herbert, University College.
Thompson, J. B., Owens College and Manchester Royal Infirm.
Tubby, Alfred Herbert, Guy's Hospital.
Tunstall, John Ogle, University College.
Vincent, Herbert Edmund, Guy's Hospital.
Wheatley, James, King's College.
Wheaton, Samuel Walton, St. Thomas's Hospital.
Williams, William Griffith, St. Bartholomew's Hospital.
Wynter, Walter Essex, Middlesex and St. Bartholomew's Hosps.

SECOND DIVISION.

Bailey, William Henry, St. Bartholomew's Hospital.
Chapman, Harry Cecil, St. Bartholomew's Hospital.
Clegg, J., Owens College and Manchester Royal Infirmary.
Colman, W. Stacy, University of Edin. and University College.
Crouch, C. Percival, St. Bartholomew's Hospital.
Fisher, Theodore, Guy's Hospital.
Furnivall, Bryan, St. Bartholomew's Hospital.
Gault, A. H., Owens College and Manchester Royal Infirmary.
Heatherley, Francis, Guy's Hospital.
Jordan, W. Ross, Birmingham Medical School.
Luff, A. Pearson, B.Sc., St. Mary's Hospital.
Mumford, A. A., Owens College and Manchester Royal Infirm.
Napier, Francis Horatio, St. Bartholomew's Hospital.
Pagden, Trayton Charles, St. Bartholomew's Hospital.
Randall, Ernest Bidgood, University College.
Strugnell, Walter T., St. Bartholomew's Hospital.
Watson, W. Ivens Buswell, Guy's Hospital.
Wells, George Lee, St. Bartholomew's Hospital.
Williams, Reginald Muzio, St. Thomas's Hospital.

UNIVERSITY OF GLASGOW.—The following degrees were conferred in the various Faculties of the University on the 17th inst.:—

DOCTORS OF MEDICINE.

1. COMMENDED FOR THESES.—John Brown, M.B., C.M., Scotland; John Love, M.B., C.M., Scotland.
2. ORDINARY DEGREE.—Quintin Chalmers, M.B., C.M., Scotland; W. Rees Jones, M.B., C.M., Wales; Alex. Morison, M.B., C.M., Scotland; James Foster M'Conaghy, M.B., C.M., Ireland; Ernest Mackenzie, M.B., C.M., England; Alex. Scott, M.B., C.M., Scotland.

BACHELORS OF MEDICINE AND MASTERS IN SURGERY.

1. COMMENDATION.—Gavin Russell, Scotland.
2. ORDINARY DEGREES OF M.B. AND C.M.—Alex. Butler, Archibald Campbell, J. Dobbin, W. R. Forrester, R. Jardine Freebairn, Daniel Laird, G. Lapraik, J. M'Corkindale, Thomas Longlands Macfarlane, David Johnston Penney, and J. W. Watkin Penney, all of Scotland.

CONJOINT EXAMINING BOARD OF THE COLLEGE OF PHYSICIANS IN IRELAND AND THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following, having passed their final examinations, have received diplomas qualifying them to practise Medicine, Surgery, and Midwifery:—

Edward W. Mahaffy Adair, James J. Behan, B. J. Dore, John David Ferguson, Robert Eustace Hickie, Leonard Kidd, H. Alban Marsden, James Martin, Denis Patrick Murphy, James O'Connor, Jeremiah O'Sullivan, John Dwyer Sexton, T. Stephen Sillis, and J. Trant.

COLLEGE OF PHYSICIANS IN IRELAND.—At the November examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—Martin Fitzgerald.
MIDWIFERY.—William Morris Lewis.

The undernamed have been admitted Members:—

George Richard Armstrong, Richard Cannon, William Malcomson.

UNIVERSITY OF OXFORD. — The Professor of Anatomy, Mr. Moseley, is incapacitated at present by ill-health from the performance of his duties, and Convocation is asked to grant him leave of absence for the ensuing year. Mr. S. J. Hickson, of Downing College, Oxford, has been appointed his deputy.—On the 17th inst. the degree of M.B. was conferred on Herbert Pennell Hawkins, Pembroke.

A NEW WARD has just been added to the Beccles Hospital as a permanent memorial of the Jubilee.

BEAVEN RAKE, M.D. Lond., has been appointed a Justice of the Peace for the Western District of the County of St. George, Trinidad.

NATIVE HOSPITAL IN ANNAM. — A hospital for natives is being constructed on the right bank of the river at Hué, near the French Legation.

QUADRUPLETS.—The wife of a fisherman of Austin-street, King's Lynn, has just been delivered of four children, all boys. Three of them were born alive, but one of the three died shortly afterwards.

NEW CHILDREN'S HOSPITAL IN PARIS. — The new children's hospital in Paris, which is to be called the Debrousse, for the erection of which the Baroness Alquié left two millions of francs, is to be built in the rue Bagnolet.

MEDICAL MAGISTRATE.—Mr. E. Godson, M.R.C.S., superintendent of the Hospital for the Insane, Parramatta, New South Wales, has recently been elevated to the bench of magistrates for the division.

PRESENTATION. — Surgeon-Major John Blackburn has been presented with a silver salver by the members of the Monckton Main Colliery St. John Ambulance Class, in recognition of his gratuitous instruction in rendering first aid to the wounded.

CHURCH OF ENGLAND BURIAL REFORM ASSOCIATION. The ninth annual meeting of the members of this Association will be held in St. Paul's Chapter Room on the 12th prox. at 3 P.M., the Right Rev. Bishop Suffragan of Bedford in the chair.

DEATH OF A MEDICAL MAN FROM HYDROPHOBIA.—A French medical man, Dr. Cauvy of Béziers, has just died from hydrophobia. He was bitten by a rabid dog some three months ago, and immediately went to Paris and underwent the inoculation treatment.

THE COUNTESS OF DUFFERIN'S FUND.—The Countess of Dufferin reports the result of the collection for the benefit of Indian women, through the National Association, to be the realisation of 478,465 rupees in India and £1770 in England.

PRESCRIPTIONS OF RUSSIAN SURGEON-DENTISTS.—The Russian Medical Council has rejected the request addressed to it by the Society of Surgeon-Dentists praying for the abrogation of the law forbidding these practitioners to prescribe "violent" medicines.

GLASGOW ROYAL INFIRMARY MEDICAL SOCIETY.—The introductory meeting of this Society was held on the 19th inst., when Dr. Wallace Anderson read a paper on Observations on the Study of Disease, being his valedictory address as honorary president. Dr. Fleming is the president for the ensuing year.

CHILDREN'S JUBILEE HOSPITAL AT GATESHEAD.—The foundation stone of the Children's Jubilee Hospital at Gateshead is arranged to be laid on December 2nd. It is intended at present only to proceed with the central administrative block and one of the wing wards, but the whole scheme includes four of these wards. The administrative block is estimated to cost £2000, and each of the wing wards about £1000, or a total of about £6000.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

DOWNMAN, CHARLES F., M.R.C.S., has been appointed Medical Officer for the Burnham District of the Maldon Union.

HILLIARD, R. HARVEY, M.D., F.R.C.S.E., has been appointed House-Surgeon to the Bucks General Infirmary.

KEMP, BENJAMIN, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Horbury Urban Sanitary District, Yorkshire.

MAHON, RALPH BODKIN, has been appointed Demonstrator of Anatomy, and Assistant to the Professor of Physiology at the Queen's College, Cork.

MOXHAM, M. CAMPLIN, M.R.C.S., L.R.C.P., L.S.A., has been appointed House-Surgeon to the Stroud General Hospital, vice C. E. Liesbing, M.R.C.S., L.R.C.P., resigned.

PARROTT, T. G., M.R.C.S., L.R.C.P. Lond., has been appointed House-Surgeon to the Bucks General Infirmary, vice R. W. Wilcox, M.R.C.S.

ROWNTREE, WILLIAM GEORGE, L.R.C.P. Ed., M.R.C.S., has been appointed Medical Officer for the Thornhill District, and Public Vaccinator for the Barnsbury and Thornhill Wards of the Parish of St. Mary, Islington, vice Whiteway Wilkinson, F.R.C.S., retired.

SIBLEY, WALTER K., B.A., M.B., B.C. Camb., M.R.C.S., has been appointed House-Physician to the Middlesex Hospital.

SMITH, SAMUEL GORDON, M.R.C.S., L.S.A., has been appointed Medical Officer for the Barnsbury District of the Parish of St. Mary, Islington, vice W. G. Rowntree, transferred.

WELCHMAN, E. W., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the St. Mary District of the Lichfield Union.

WILSON, MERVYN, M.R.C.S., L.S.A., has been appointed Medical Officer for the Chippenham District of the Chippenham Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BRISTOL FORESTERS' MEDICAL INSTITUTE.—Two Medical Officers.—Resident Dispenser.

BROMLEY AND BECKENHAM JOINT HOSPITAL BOARD.—Medical Superintendent. Salary about £70 per annum.

BROMLEY UNION, Kent.—District Medical Officer. Salary £85 per annum, vaccination fees and extras about £35.—Medical Officer for the Union Workhouse. Salary £90 per annum, vaccination fees and extras about £25.

BURTON-ON-TRENT INFIRMARY.—House-Surgeon. Salary £130 per annum, with a prospect of increase, and rooms, coals, and gas free.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House-Surgeon.

CITY OF LIVERPOOL HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Officer. Salary £100 per annum, with board, washing, and lodging at the hospital.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Obstetric Physician to Out-patients.

HULL ROYAL INFIRMARY.—Honorary Dental Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £30 per annum, with furnished apartments, board, attendance, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Assistant Physician.

NEWPORT (MON.) ODDFELLOWS' MEDICAL AID ASSOCIATION.—Medical Officer. Salary £140.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiner.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor, Isle of Wight.—Resident Medical Officer. Salary £100 per annum, with board and lodging in the hospital.

ST. GEORGE, HANOVER-SQUARE, PROVIDENT DISPENSARY, Little Grosvenor-street, W.—Resident Medical Officer. The salary and allowances last year were £235 8s.

ST. GEORGE'S HOSPITAL, Hyde-park Corner, W.—Physician.—Surgeon.

STOCKPORT INFIRMARY.—Assistant Medical Officer. Salary £50, with board and lodging.

UNIVERSITY OF EDINBURGH.—Examiners in the Practice of Physic, Midwifery, Anatomy, and Chemistry. Salary in each case £75 per annum, with an allowance of £10 for expenses.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea.—House-Physician. Honorarium £50 per annum, and board and lodging in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

GLASIER.—On the 16th inst., at Eastbourne, the wife of Charles Glasier, M.D., of a daughter.

HALL.—On the 17th inst., at Wimpole-street, W., the wife of F. de Havilland Hall, M.D., F.R.C.P., of a son.

JESSOP.—On the 20th inst., at Retford, the wife of Ed. Jessop, M.R.C.S., L.R.C.P., of a son.

LEECH.—On the 22nd inst., at Woolpit, Suffolk, the wife of A. Herbert Leech, M.R.C.S.E., L.S.A., of a son.

NANKIVELL.—On the 15th inst., at Penmellyn, Bournemouth, the wife of Herbert Nankivell, M.D., of a daughter, who survived her birth only three hours.

RUSHWORTH.—On the 17th inst., at Beechfield, Walton-on-Thames, the wife of Norman Rushworth, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

DIMMOCK—ALLEN.—On the 16th inst., at St. Peter and St. Paul's Church, Cremer, Augustus Frederick Dimmock, M.B., M.R.C.S., to Laura, eldest daughter of the late John Bonfield Allen, of Fairfield House, Norwich.

FOSBROKE—LANE.—On the 15th inst., at the Parish Church, Dorsington, G. H. Fosbroke, M.R.C.S., L.S.A., S.Sc.C. Cantab., to Mary Thorpe, second daughter of the late John Lane, Esq., of Little Dorsington Manor.

MYRTLE—SMITH.—On the 23rd inst., at St. James's Church, Westbourne-terrace, James Aitken Myrtle, M.D., C.M., to Jane Cranfurd, daughter of Thos. Smith, Esq., of Edinburgh.

DEATHS.

DAVIES.—On the 19th inst., at Penner House, near Newport, Monmouthshire, Arthur Evelyn Davies, M.R.C.S., L.R.C.P., L.S.A., aged 38.

FRANKLIN.—On the 5th inst., at Brighton, Charles Franklin, M.R.C.S., L.S.A., of Putney, S.W., aged 45.

MARRIOTT.—On the 18th inst., Fredk. Thos. Marriott, L.S.A., of Old-street, City, London, aged 50.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE LEPERS OF MOLOKAI.

MOLOKAI, "the leper island of the Pacific," is one of the Sandwich group, and the scene of Father Damien's heroic labours. By far the best description of that home of the banished leper and of the missionary care bestowed on him is that by Mr. Charles Warren Stoddard, one of the most painstaking, and at the same time picturesque, of contemporary transatlantic writers. From the little volume (published at Notre Dame, Indiana, U.S.) we gather that there are always between 700 and 800 lepers in the settlement, and that the average death-rate is 150 per annum. Within the last fifteen years 2500 of these afflicted ones have been segregated to Molokai. The sketch of Father Damien himself is entitled to take rank with Manzoni's portrayal of Cardinal Borromeo, in the "Promessi Sposi." The Father's experiences, as told by Mr. Stoddard, who was his guest in the leper island, add force to the saying, "Truth is stranger than fiction."

M.D. (Highgate).—Information on the subject will be found in the Australian Medical Directory and Handbook, published by Baillière, Tindall, and Cox, King William-street, Strand.

Mr. J. G. Smith (Liverpool).—The matter is of obvious importance; but we are unable at present to devote further space to its discussion.

Dr. L. Corazza (Verona).—The address is, Grant Medical College, Bombay.

"WHAT MUSCLES ACCOUNT FOR IT?"

To the Editors of THE LANCET.

SIRS,—In answer to the inquiry of your correspondent, "M.D., C.M.," I beg to say that the difficulty is not with regard to the muscles concerned—for vomiting is a coördinated action, the efferent impulses concerned in which proceed from a vomiting centre in the medulla in close connexion with the respiratory centre,—but with the independent power of the will to stimulate this centre. We know that some disagreeable sights and smells may readily affect it, and here the will has no control; but in this case the act is preceded by a sensation of nausea, and is therefore probably reflex. The only explanation I can offer is that your correspondent's case is an example of a physiological reversion to an ancestral condition. In the ruminantia the stomach is divided into four compartments, and after the food has lain in that division of it termed the "reticulum" for some time at the will of the animal, the partially masticated food is returned by small instalments to the mouth, and is there thoroughly chewed at leisure, and then swallowed for the second time. It is to be remembered that we all possess a relic of our herbivorous co-ancestry in the presence of an appendix vermiformis.

I am, Sirs, faithfully yours,

E. KENNETH CAMPBELL, M.B., F.R.C.S.

Lincoln's Inn-fields, W.C., Nov. 22nd, 1887.

Digitized by Google

LEICESTER PROTECTED BY VACCINATION.

Mr. Biggs.—We must be satisfied in the first instance of the composition of the committee in point of principle. The *personnel* is a secondary matter. But we shall be quite ready to name a representative when the consent of other parties who would command public confidence to the constitution of the committee has been assured.

F.R.C.P. Edin.—So far as we are aware, the full address has not been published.

Mr. W. H. Pépler will find the information he desires in the Transactions of the Epidemiological Society for the session 1885–86.

Dr. G. W. Balfour.—The discussion of the question must be considered as closed.

"STRUMOUS ULCERS."

To the Editors of THE LANCET.

SIRS,—If your correspondent, "M.B.," will give the following plan a fair trial, I believe he will find the result satisfactory.

1. Cease administration of all tonics (including cod-liver oil). 2. Bathe the sores daily with warm water, so as to remove scabs and as much discharge as can be washed away. 3. Dress with old linen rag, dry, or soaked with sweet oil to facilitate removal. 4. Administer three times a week at bed-time from one to two grains of calomel, and every morning, half an hour before rising, a saline draught containing mag. sulph., ʒ i.; mag. carb., gr. x.; pot. nit., gr. v., in peppermint water. 5. Persist in the treatment for three months, longer if necessary, omitting the calomel one week in every four.

This method practically means the substitution of constitutional for local treatment. It is neither new nor original; but I have found the plan succeed when other approved modes of treatment have failed.

At the Willan Society, in October, I showed two cases about to be placed under this treatment. This month one of these patients again attended, the other being invited but failing to come. In the month both patients had gained in weight and felt stronger. Some of the lesions had cicatrised; the others showed signs of healing. When seen last Wednesday the progress continued; and I shall be glad to show your correspondent the cases if he will communicate with me.

I am, Sirs, yours faithfully,

Suffolk-street, Pall Mall, S.W., Nov. 19th, 1887. ARTHUR HARRIES.

To the Editors of THE LANCET.

SIRS,—In response to "M.B.'s" request as regards strumous ulcers of the neck, I may say that they are very troublesome to heal, as the treatment requires variation from week to week; but the following line of treatment might be tried.

If the sores are coated with scrofulous matter this must be scraped off. Then dust with plumbi iodidi daily, if sluggish and they do not seem to improve. Take a piece of cotton-wool, twist round a probe, and apply a solution of chloride of zinc (one drachm to an ounce of distilled water) each day. Pick off the scab. Sometimes the cerat. resina has a wonderful charm; other times cerat. resina and ungt. plumbi acet. part. æquale. The patient must be treated constitutionally either by cod-liver oil, syrup of hypophosphites, or equal parts of syrup. ferri phos., syrup hypophos., ʒ ss. ter die. I am, Sirs, yours faithfully,

Nov. 19th, 1887. F.R.C.S.

OINTMENT FOR USE IN SMALL-POX ERUPTION.

DR. J. M. REDMOND, Physician to Cork-street Fever Hospital, Dublin, informs us that he has been using, with apparently good results, the following as an application to the face in cases of small-pox:—℞ Acidi boracici, gr. 40; lanolin and adipis, ää ʒss. Ft. ungt. M.

Dr. Bowden (Chatham).—We should be glad to receive the reports of the cases mentioned, especially of the first, second, and fourth.

Mr. White Wallis.—An article in our last issue includes all the points in our correspondent's letter.

BURIAL REFORM.

To the Editors of THE LANCET.

SIRS,—Will your correspondent, "F. H. W.," kindly send me his name and address, that I may invite him to the ninth annual meeting of the Church of England Burial Reform Association, to be held on Monday, Dec. 12th, at 3 P.M., in the St. Paul's Chapter-room, E.C., the Bishop of Bedford in the chair. For the information of your readers generally, permit me to say that the Burial Reform Association aims at uniting ministers of religion, medical men, and scientists generally in the effort to bring back the nation to the Church's mode of burial—namely, that indicated by the words "earth to earth," and this on grounds both sanitary and economic; and that we shall be very thankful for co-operation of any sort.

I am, Sirs, faithfully yours,

F. LAWRENCE,

Hon. Sec. Church of England Burial Reform Association.

Weston Vicarage, York, Nov. 21st, 1887.

LARYNGEAL SPASM WITH ASSOCIATED NERVE SYMPTOMS.

To the Editors of THE LANCET.

SIRS,—If your correspondent, "M.B.," will try inhalations of amyl, I think he will find it suit his patient.—I am, Sirs, yours faithfully,

Nov. 21st, 1887. G. B. B.

SOLANINE.

J. V. (Hamburg).—This therapeutic agent, discovered in 1820 by Desfosses, a pharmacist of Besançon, and first applied to medical uses in 1859 by Clarus of Leipsic, had fallen into desuetude when its efficacy was once more tested by Drs. Geneuil and Bardet in the Cochin Hospital of Paris. These investigators found it very difficult of administration by the hypodermic method, as it is nearly insoluble in water, in ether, and in alcohol. It was therefore exhibited through the digestive tract in rice-wafers and pills. It was tried in sciatic neuralgia (in doses of from thirty to forty centigrammes daily); but after being carefully observed for seven days its action was found *nil*. In rheumatism it was prescribed with more success; but in gastralgia, accompanied or not by vomiting, as also in facial neuralgia and in angina pectoris, its pain-relieving virtues were not encouraging. With morphine and atropine it cannot be compared for a moment in certainty and rapidity of effect.

Ambulance.—There is a section on the subject in Sir J. Paget's Clinical Lectures and Essays, edited by Mr. Howard Marsh. There are also Cazalet's and Klencke's works.

Dr. James Johnston's letter is a little out of date. The regimental system is irrecoverably defunct.

A QUESTION OF OFFICIAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—At page 960 of your issue of Nov. 12th is a report of a case of general paralysis of the insane which the reporter says was under his care. The reporter is Mr. Mortimer, assistant medical officer of the Portsmouth Lunatic Asylum, in which asylum the case was treated, and of which institution Mr. W. C. Bland, M.R.C.S., is the medical superintendent. With your kind permission, I will point out that an assistant medical officer, as a person responsible for the care of a lunatic in an asylum, does not exist at law. The 55th Section of the Lunacy Act of 1853 empowers the visitors of an asylum to appoint a medical officer, who may also be superintendent. Mr. Bland holds both offices. Therefore the case was under his care, and not Mr. Mortimer's. It may interest Mr. Mortimer to know that the Commissioners in Lunacy insist that assistant medical officers are in no way responsible for the medical and surgical care and treatment of lunatics in an asylum, that responsibility resting, as it does, on the statutorily appointed officer, the medical superintendent. I am, Sirs, yours faithfully,

Stapleton, Nov. 14th, 1887. GEORGE THOMPSON, M.D.

A CENTENARIAN.

WITH reference to the case of longevity recorded at page 947 of our issue of Nov. 5th last, a correspondent informs us that he has seen a certified copy of the entry in the baptismal register of the parish church of Hodnet in this county, to the effect that the said Charlotte Pigot was baptised on July 9th, 1785, thus proving beyond question that this was a veritable instance of a woman who on Oct. 9th, 1887, had well entered upon her 103rd year.

Alpha is quite eligible to be elevated to the bench; but he must not act as an *ex-officio* guardian while he holds his appointment as Poor-law medical officer.

ELIXIR OF SACCHARINE.

To the Editors of THE LANCET.

SIRS,—A convenient fluid preparation of saccharine being required for dispensing purposes, as chairman of the Formulary Committee of the Pharmaceutical Conference, I have been requested by some of its members as a provisional formula to recommend the following for elixir saccharini:—Take of saccharine, 24 gr.; bicarbonate of sodium, 12 gr.; rectified spirit, 1 fluid drachm; distilled water, 7 fluid drachms. Rub the saccharine and bicarbonate of sodium in a mortar, with the water gradually added. When dissolved, add the spirit, and filter. Twenty minims contain one grain of saccharine. This is sufficient to flavour a four-ounce mixture. I am, Sirs, yours obediently,

New Cavendish-street, W., Nov. 17th, 1887. WM. MARTINDALE.

THE PRIORITY OF LARYNGECTOMY.

To the Editors of THE LANCET.

SIRS,—In the interesting "Chronicles of the Cumming Club," by Lt.-Col. Alexander Ferguson, recently published in Edinburgh, at p. 216 occurs the following statement with reference to Dr. Patrick Heron Watson:—"He cut out the larynx before the operation was performed in Germany, where it is supposed to have originated." Is such assertion a correct one? I am, Sirs, yours truly,

New University Club, Nov. 22nd, 1887. J. C. G.

COCAINE IN MIDWIFERY.

To the Editors of THE LANCET.

SIRS,—Some months ago a letter appeared in THE LANCET stating that the writer had used cocaine successfully in twenty cases of midwifery. Can anyone tell me how the cocaine is used, and to what extent it is successful? I am, Sirs, yours faithfully,

November 11th, 1887. G. P.

Medical Diary for the ensuing Week.

Monday, November 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Mr. H. H. Statham: The Elements of Architectural Design. (Cantor Lecture.)
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The following cases will be shown:—Mr. Bowreman Jessett: Two cases of Radical Cure of Hernia.—Dr. Ormerod: Case of Hysterical Tremor and Contracture.—Mr. Walter Pye: (1) Case of Persistent Branchial Cleft; (2) A New Form of Truss.—Dr. Savill: Case of Myxœdema in a Male.—Dr. Beevor: Case of Myxœdema.—Dr. Herringham: Case of Dizziness.—Mr. Spencer Watson: Case of Plastic Operation for Ectropion.—Mr. Marmaduke Sheild: Case of Syphilitic Disease of the Knee-joint.

Tuesday, November 29.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

Wednesday, November 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-ST.—Operations, 9 A.M.; Saturday, same hour.

Thursday, December 1.

ST GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
THE PARKES MUSEUM OF HYGIENE.—5 P.M. Sir Douglas Galton: Smoke and Fog.

Friday, December 2.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn: A large Hæmorrhage into the Pons Varolii, and other Pathological Specimens.—Mr. Samuel Benton: Remarks on the Successful Treatment of Habitual Constipation by the use of Injecto-purgative.—Dr. Savill: Cases illustrating his paper, *vide infra*. The Bowman Lecture

ON THE

RELATION OF OPHTHALMIC DISEASE TO CERTAIN NORMAL AND PATHOLOGICAL CONDITIONS OF THE SEXUAL ORGANS.

Delivered at the Ophthalmological Society, Nov. 11th, 1887,

BY HENRY POWER, M.B. LOND., F.R.C.S.

(*Concluded from p. 1053.*)

THE occurrence of a reflex action between the ovary and the eye, though in itself highly probable, is difficult to establish, because there are so many contingencies, and the path through which the noxious influence travels is difficult to trace. The following case is, however, one in which I thought that such a connexion existed.

A young lady, married, but childless, applied to me stating that she had experienced considerable pain over the right brow, and that dimness of the right eye had at first annoyed, and as it increased in intensity alarmed her, and that she had just discovered she was blind with this eye. On examination, I found the right pupil slightly dilated, very sluggish in response to light, and vision reduced to mere perception of light. There was slight eversion of the right eye. The left eye was normal, pupil acting well, and vision $\frac{2}{3}$. On ophthalmoscopic examination the disc of the right eye was found to be swollen and reddish, with ill-defined margins—in short, with the general aspect of optic neuritis. She informed me that about nine months previously she had suffered from an attack of ovariitis, for which active treatment was adopted, and she was confined to her room for some time. Having been married for a year or two without family, and thinking there might be some mechanical obstacle, she placed herself under the care of a distinguished gynæcologist, who passed a sound into the uterus, causing considerable pain, about two months previously. I prescribed iodide of potassium for her, directed her to rest at home, and gave general directions for her diet. During the next succeeding few days she complained of a feeling of coldness and numbness of both sides of her body. Improvement in vision took place almost immediately after commencing the use of the iodide, and in less than a week she was able to count the fingers, and to see large objects to the temporal side of the right eye. The urine was loaded with lithates. A consultation was held, and it was agreed to rub in mercury till the gums were touched; 1300 grains were required for this purpose, about half a drachm being rubbed in night and morning; steady improvement took place, the field of vision gradually extending till it became nearly normal. She herself called attention to the circumstance that within a small area—about fifteen degrees to the outer side of the point of fixation—pink objects appeared green. This area corresponded nearly to the region of the optic disc, but she was very positive about its occurrence. About four months afterwards, strychnine and iron having been taken with intermissions in the interval, she stated that she was perfectly well, and could see almost as well with the right as with the left eye, though it was slower of perception, so that she had to look for an appreciable time before the words became visible. The pupil had recovered its natural activity.

At first sight this case appeared to be one of hysteria, and in the pre-ophthalmoscopic period would undoubtedly have been diagnosed as hysteria. Dr. Hughlings Jackson, who saw the case with me, was quite satisfied of the existence of the neuritis. The family history was good. It seems to me that one of two suppositions is open to us: either that some coarse disease of the brain was in progress, which is to some extent negatived by the great improvement that has taken place; or that, as I believe, there was some reflex irritation proceeding from the old ovariitis, perhaps lighted up by the passage of the sound.

In similar hysterical cases, where great disturbance of vision accompanied with great pain have occurred, iridectomy has been resorted to in the hope of affording relief. A case of this nature has been recorded by Cuignet.[1] This case was remarkable for the fluctuations it presented, the patient, whose vision was at first almost abolished, being able to see with a smoked glass, then requiring a + 2 D, then a concave glass, the ultimate result being complete loss of vision in the eye affected.

It is not surprising that the profound changes effected in the female organism by the supervention of pregnancy should betray themselves by some alteration in the structure and functions of the numerous and complicated tissues of the eye. Physiological researches have shown that at this period there is considerable increase in the absolute volume of the blood, the development of the wide sinuses of the uterus requiring so large a quantity of blood to fill them that a state of anæmia in other organs would otherwise occur, as indeed is sometimes seen when this part of the process is imperfectly performed. At the same time the quality of the blood undergoes considerable alteration, which, though it may fit it for the retention of the fœtus, is certain to exert a marked influence on other organs and tissues. The most remarkable of these changes is that the red corpuscles and the albumen diminish, whilst the water, white corpuscles, and fibrin increase. Hence the specific gravity of the blood, as a whole, is diminished, and there is a deficiency in the solid constituents of the serum, probably owing to their being taken up by the fœtus. The increase of the fibrin and of the white corpuscles may perhaps be explained by the growth and development of the lymphatic system of the uterus and of the glands of the uterus, occasioning what has been termed by Virchow a physiological leucocytosis. In accordance with this condition of general plethora of the vascular system with thinner blood, the heart, having to drive a greater volume of fluid through a larger area, undergoes an hypertrophy of the left ventricle; and to the combined conditions of diluted blood, wider vascular area, and a more powerfully beating heart, some, at least, of the more common symptoms of pregnancy are due—as, for example, palpitation, tendency to syncope, and nervous irritability; numerous phenomena on the side of the digestive apparatus—as dyspepsia, anorexia, and morning sickness; and, lastly, various modifications of the urinary function, the urine being usually increased in quantity, and being found in a large percentage of cases to contain albumen. It is, indeed, stated that albumen appears in the later months of pregnancy in 20 per cent., and in a still larger proportion of primiparæ.

One of the subjective defects of vision that is first and very commonly observed by the patient in pregnancy is loss of the power of accommodation. She finds herself unable to read or work for more than a few minutes; letters and lines run together; pain in the eye or brow, sometimes of an acute character is felt, and the book is laid down, not to be again taken up. This symptom, due to imperfect nutrition of the ciliary muscle and of the third nerve, probably depends on the watery state of the blood, and belongs to the same category as the vertigo and fainting that are occasionally observed in pregnant women, though it may be of a reflex nature, and comparable with the amblyopia seen in cases of dental disease. The earliest period at which I have met with it has been at the eighth week, and in this case it occurred in a patient whose refraction was normal; but it is most common in the later months. It is to be relieved in two ways: first, by attention to the general health, the administration of tonics, the regulation of the bowels, and systematic, if brief, out-door exercise; and, secondly, by the temporary employment of weak convex glasses. The symptom is earliest and most strongly felt by the hypermetropic patient, and the strength of the glass must of course be proportionate to the degree of hypermetropia present.

Again, the great lassitude and debility which affect many women, the result of the disturbance of the digestive organs, renders them peculiarly susceptible to the influence of cold. I saw a woman thirty-two years of age, who came to me with intense congestion of the conjunctivæ, which she stated had recurred after exposure to cold with each of her five previous pregnancies near the time of her confinement, and other authors have noticed that liability to attacks of conjunctivitis characterise this period.

In all instances where the nutrition of the body is badly maintained, either from an inadequate supply of food or from imperfect digestion and assimilation, so that the blood becomes thin and poor, those parts of the body which are most remote from the blood supply are apt to suffer. The cornea is one of those parts, and we accordingly find that ulcers of the cornea sometimes occur in pregnancy. Whether the ulcer results from simple disintegration and decadence of the superficial epithelial layers of the cornea, or whether these cells, being imperfectly developed and preserved, yield to external influences—such as the attacks of micro-organisms, which under ordinary circumstances they are capable of resisting,—it is difficult to say. Perhaps both conditions coexist, and lead simultaneously to the formation of the ulcer. I believe that pregnancy is a predisposing cause to lacrymal abscess, the morning sickness, by inducing congestion of the head, putting a finishing touch to a nearly closed nasal duct, and effecting its complete occlusion.

Amongst the functional disturbances that are apt to accompany both dysmenorrhœa and the process of pregnancy is the condition formerly named *hebetudo visus*, in which there is heaviness of the lids almost amounting to ptosis, inability to face light, and indisposition to exert the power of accommodation by attention to any kind of near work. In many instances, no doubt, these effects are due to failure of the power of accommodation in a hypermetropic eye, but, as Förster remarks, a certain number of cases remain, where this complication is excluded, in which the failure of power is due to a reflex hyperæsthesia of the fifth nerve and of the optic nerve, and constitute an aggregate of symptoms to which the term "kopiopia hysterica" may be applied. Förster devotes quite a long chapter to this subject. He points out that the hyperæsthesia of the fifth nerve leads the patient to use exaggerated terms in describing her ailments, and causes her to continue to complain of pain and discomfort even when any slight defect of hypermetropia or presbyopia has been corrected. The glasses increase the pain, or the frames are too heavy, or she sees too acutely and clearly with them. The implication of the optic nerves is indicated by the patient complaining of light, and especially of artificial light, which, she states, irritates her eyes much more than the diffused yet more brilliant light of day. During the day such patients can walk out without inconvenience, but with the entrance of the lamps they insist that it is essential to their comfort that they should have darkened glasses. Förster believes this peculiar form of intolerance of light, which is characterised by the absence of any well-marked tendency to lacrymation, is due to intolerance of differences of illumination of objects in the field of vision, which is much more noticeable by artificial than by natural light.

That the congestion of the head which results from the severe retching and vomiting that so often accompanies the early months of pregnancy may induce hæmorrhage upon the retina, the following case, of which a drawing was taken by Miss Boole, will show. The patient was twenty-nine years of age; had married at nineteen, and had had five children, four of whom were living. Her eyes had been perfectly healthy up to five weeks previously, when, after a violent effort of retching in the evening, her eyes felt dazzling and every object was wavy. The next morning, on rising, she discovered that she could only see objects above the horizontal plane, and this defect was permanent. Ophthalmoscopic examination revealed the large hæmorrhage, with rounded contours, close to the disc and to its outer side, shown in the drawing. The patient was examined by Dr. Godson, who pronounced her in the sixth month of pregnancy. The urine was carefully tested by Dr. Bullar, and contained neither sugar nor albumen.

Puzzling cases occur every now and then in the early months of pregnancy, which, however, point to embolism as the cause of the symptoms. For example, a patient aged twenty-eight, in the third month of pregnancy, suddenly noticed that her vision was lost below a line running obliquely from the temple to the nose in the right eye. The most careful examination by more than one ophthalmic surgeon of repute failed to discover the slightest defect or disease in the eye. She had had severe headaches, and also some choreic movements of the facial muscles and of the arm of the right side, three weeks previously. The urine was perfectly free from either albumen or sugar. It was remarkable that pressure on the globe gave distinct phosphenes on the non-sensitive part of the retina. Six or seven years have elapsed, and the only change noticeable is that the disc on the right side is whiter than on the left.

In the later months of pregnancy another affection is sometimes observed, which has been frequently described, is of a serious character, and is deserving of special attention both on account of its value as an indication of the condition of the patient and for the special treatment that it suggests. It is a condition that very closely resembles, and is perhaps identical with, albuminuric retinitis. The patient does not usually complain of impairment of vision until well-marked retinal changes are visible on ophthalmoscopic examination. These changes consist in swelling of the optic disc, rosiness of its surface, indistinctness and blurring of its margin, enlargement and increased tortuosity of the retinal vessels, their point of emergence from the disc being concealed by effusion, hæmorrhages of large and irregular form, and white patches, which are sometimes irregularly scattered over the surface of the retina, and sometimes arranged in a radial manner around the yellow spot. The onset of the disease is often sudden, and accompanied by headache, flashes of light, and other symptoms of retinal irritation. Vision may be reduced to perception of light only, or to the power of counting the fingers. These symptoms are associated with the appearance and continued presence of albumen in the urine, and this condition has been described by gynæcologists as gravidic albuminuria. It is often a precursor of convulsions. The phenomena of uræmic eclampsia with ophthalmic symptoms were first brought under the notice of the profession in England by Dr. Matthews Duncan, in a translation made in 1857 of Braun's memoir on the subject. In accordance with the received pathology of that day, the symptoms were attributed to the presence and decomposition of urea in the blood; and, in giving a graphic description of the symptoms of the attack, Braun remarks that it is sometimes preceded by mental illusions, photopsiæ, and amblyopia, and that it may terminate in complete blindness.

The conditions which may lead to the appearance of albumen in the urine are very various. Dumas[2] collects them under three heads—viz., increase of intravascular tension, qualitative alteration of the blood, and temporary or permanent disease of the kidney. Others have suggested that there may be in some cases catarrh of the lower part of the neck of the uterus, and it is quite possible that two or more of these causes may co-operate in producing the symptom. The great derangement of the processes of digestion that occurs in pregnancy lends a high degree of probability to the view that changes in the composition of the blood, consequent on the absorption of imperfectly digested proteids, exert a powerful influence in inducing albuminuria, whilst the fact that it is particularly common in twin pregnancies lends support to the idea that pressure on the renal veins and local disturbances of the circulation may play their part in its production.

The appearance of albumen in the urine in pregnancy is most common about the eighth or ninth month; but it has been seen by Ollivier in the third month, and by Bach as early as the sixth week. The duration of the attack, according to Hofmeier, is usually five or six weeks. Gravidic albuminuria usually rapidly disappears after delivery. The ophthalmic trouble also usually commences in the later months of pregnancy, though Rayerson[3] reports a case in which it occurred in the fourth month. If pregnancy proceeds, the ophthalmic affection becomes more marked and manifest till delivery takes place, before which period no improvement can be expected to occur.

The history of all these cases is similar. I give one that I saw with Mr. Ambler of Hempstead House, Hemel Hempstead. The patient was a young woman aged twenty-seven, and applied to Mr. Ambler in the third month of her pregnancy, complaining of vomiting and great pain in her head, chiefly confined to the occipital region, constipation, and swelling of the legs and ankles. The urine, on being tested, was found to contain one-sixth albumen. Mr. Ambler prescribed hot baths, diuretics, and tonics, and compound jalap powder every other morning. The patient became steadily worse, and her friends were told she had little chance of going her full time. She suffered much from sleeplessness, for which chloral hydrate and digitalis were given to her. Albuminuric retinitis commenced about the sixth month of pregnancy. The constitutional symptoms became so severe about the seventh month that Mr. Ambler

[2] Thèse, 1880. [3] Gaillezowski's Recueil, 1883, p. 623.

Digitized by Google

made up his mind to induce premature labour, and this was, with the consent and approval of Dr. Russell Steele, about to be done, when spontaneous premature delivery took place in January, 1885, and a still-born fœtus was expelled having the appearance of having been dead a week. She made a good recovery from the labour, and for some time subsequently Mr. Ambler prescribed perchloride of iron, and the vision underwent steady improvement. When I saw her three months after her delivery, the general aspect of the fundus was that of albuminuric retinitis in the right eye, that of the left being apparently normal. The disc was ill-defined, and there were numerous white spots arranged in a radiating direction around the yellow spot. Her vision was: R $\frac{6}{18}$; L $\frac{6}{9}$. She was ordered strychnia and iron. I saw her in July, six months after her confinement. Both discs were hazy; there was some amblyopia, but the area of the field was normal. There was defective colour vision; pinks were called white, bright browns were called slate, but saturated tints were immediately and correctly recognised. On Oct. 6th, 1885, the spots, with one or two exceptions, had disappeared; the right disc was much whiter than natural, but its edges were blurred and indistinct.

Holmes[4] describes a case of retinitis with albuminuria and partial detachment of the retina occurring at the sixth month of pregnancy. There was complete loss of vision. At the end of three months vision returned after the employment for three weeks of the bichloride of mercury, but there remained complete loss of colour perception. At the expiration of three months more she recovered the power of perceiving colours, blue being first recognised, then in succession brown, red, and green.

That conditions of optic neuritis with exudation on the retina may clear up in a very remarkable manner is well known, but it is not often that an opportunity is afforded of carefully comparing the earlier with the later conditions in drawings made by a competent artist. I desire to show to the Society the two drawings taken by Miss Boole of a patient who came to me complaining of great impairment of vision in the seventh month of pregnancy. It will be seen that in the first the appearances are those of gravidic albuminuria in its highest and most intense expression. The swollen, congested, and ill-defined disc, the dilated and tortuous vessels, the hæmorrhages, and the white plaques, are all shown to perfection. Vision was then reduced to little more than mere perception of light. The quantity of albumen amounted to about one-sixth. An abortion occurred, and delivery was safely effected. And here is the other drawing by the same artist, in which but few traces of the former troubles are to be seen.

No positive statement can be made as to the ultimate results of gravidic retinitis. I have seen a case of almost perfect blindness, and also one of almost complete recovery. In some instances, again, gradual and unexpected improvement will take place in one eye, whilst the vision of the other undergoes progressive deterioration. Thus, in one case that fell under my care, a woman, aged thirty-three, had been confined of her fourth child five weeks previously. All the children were living and healthy. Two months before her last confinement, which was protracted and difficult, requiring the use of instruments, her vision became impaired. The dimness affected both eyes, and increased till she was unable to see light with the right eye. Yet she had no pain in either eye. On examination it was found that the right eye was the best of the two, vision in this eye being $\frac{1}{3}$; while she was able to spell out 14 Jaeger with the left eye, she could only count fingers at one foot. The whole field of vision in the right eye was dull, but it extended to about 50° vertically, and to about 15° horizontally, being therefore a long oval placed vertically. Her perception of colours was pretty good. On ophthalmoscopical examination the media were found to be clear. Both discs were yellowish-white, with well-defined margins and smooth level surface; no physiological pit. The retinal arteries and veins were of normal size. The choroid generally was apparently healthy. She still had considerable pain in her head.

Weber[5] observed cases which terminated in complete amaurosis; and Hirschberg has reported cases of albuminuria in which, although there were no ophthalmoscopic signs, complete blindness existed. The amaurosis, however, in his cases, proved to be temporary only, the patients ultimately making a perfect recovery.

[4] Archiv f Augenheilk., xii., 1., p. 89.
[5] Berlin. Klin. Wochens., 1873, pp. 265—279.

The conditions we are able by means of the ophthalmoscope to recognise in the interior of the eye thus furnish the obstetric physician with valuable suggestions for treatment. The existence of hæmorrhages and of white patches on the retina indicates that the normal relations between the blood, the bloodvessels, and the tissues are so modified that healthy nutrition can no longer be maintained, and that, unless speedy relief be afforded, the same or similar changes will occur in the brain, and convulsions, and perhaps death, be the result. The treatment which seems to be most promising is to promote in every way the general health of the patient; to support the abdomen with a bandage or belt, so that pressure on the kidneys, the ureters, and renal vessels may be relieved; to limit the work thrown upon the kidneys by attention to the diet and to the quantity of drink taken; to unload the bowels; and, finally, if the ophthalmic symptoms become still more marked, to induce premature labour.

Mr. Hutchinson has recorded a case which seems to point to the induction of exophthalmic goitre as a result of pregnancy. The development of the disease in this case occurred in the fifth month of pregnancy.[6]

I have only time briefly to refer to the ophthalmic symptoms that may be met with in the puerperal state. Occlusion of the vessels of the retina might be expected to occur at this period. Mr. Snell[7] has quite recently brought before this Society an interesting case of embolism of the arteria centralis retinæ of the left eye occurring two months after delivery in the course of a case of puerperal septicæmia. It was followed by white atrophy of the disc. The heart and lungs were normal, and there was neither albumen nor sugar in the urine. It was surmised, but there appears to have been no positive evidence, that the embolus proceeded from the heart. In such a case as this the mischief appears to be entirely limited to the central artery of the retina and the vascular area beyond the point of occlusion.

A form of disease occurring in puerperal women was long ago described by Hirschberg under the term "septic puerperal embolism," which is altogether a different thing from simple embolism of the central artery of the retina. It is certainly of rare occurrence, and Hirschberg[8] had only seen six cases of it. In such cases the lochia are usually abundant and offensive, and from a fortnight to three weeks after delivery rigors are experienced and pain is felt in one or in several of the joints, which suppurate. The eye presents the appearance of general ophthalmia, the conjunctiva being red and chemosed, the iris being inflamed, the anterior chamber containing pus, and vision becoming greatly deteriorated; gradually the cornea becomes hazy, the area of the pupil is filled with exudation, and vision is lost. The patient usually dies, and the fluid in the joints is found to contain bacteria, whilst the globe is undergoing suppuration, the retina and choroid being also infiltrated with pus.

Local and more or less complete pareses and paralysis of the ocular muscles are occasionally observed in the puerperal state. I have seen, for example, a case of mydriasis in a primipara of delicate and neurotic habit of body, who had been brought to bed two months previously of a child she was unable to nurse. The prime cause of the paralysis is not easy to give; it may be of a reflex nature, or be due to some local neuritis of the nerve supplying the muscle, or be the consequence of a hæmorrhage into the sheath of the affected nerve, or possibly to spasm of bloodvessels, or to embolism. Recovery is doubtful.

Various exceptional conditions may be met with. For example, I saw a case where towards the close of her time a woman complained of seeing all objects much smaller than they were naturally presented to her eyes; and I find that Churchill, Gardien,[9] and others have observed the same symptoms. Churchill observes that the patient may imagine all surrounding objects are dancing or turning round, or she may be so dizzy as to be incapable of distinct vision. These symptoms are probably connected with anæmia, or at least with disturbance of the circulation in the brain, and in general nothing can be seen with the ophthalmoscope. In other instances the patient has illusions and hallucinations, fancying that she sees objects in the air; or photopsiæ; more rarely she sees everything double.[10]

I have seen several cases in which there has been sudden loss of vision or loss of one-half of the field of vision of one

Digitized by Google

eye, without manifest ophthalmoscopic signs, though the fundus was carefully and repeatedly explored. In two of these cases which I have had the opportunity of following up, the attack was quite sudden. In one no notable change has taken place in the course of three or four years in the disc or retina. In the other, a few minute spots, supposed to be tubercular, have appeared on the surface of the retina. The cases were regarded as instances of embolism of arteries supplying a minute area of the corpora quadrigemina, or to some trouble of circulation in one optic nerve.

Several conditions of disease of the eyes are associated with lactation. In a healthy woman it is surprising how well this active and abundant secretion is borne. A more abundant diet, the constituents of which are digested and absorbed with wonderful rapidity, seems all that is necessary to enable from one to three pints of good milk to be secreted without exhaustion of the system, and this may extend over a period of from four or five to nine or ten months. There are, however, a large number of more feebly constituted women in whom the powers of the system seem to be exhausted with the effort to develop and extrude the fœtus, and in whom the mammæ fail to respond in their growth and functional activity to the cry of the child. Many women desiring to become good mothers attempt, but in vain, to give suck to their infant; and if the attempt be continued, it is not uncommon to see one of several conditions arise. In the first place loss of accommodation occurs, which is the most common. Dizziness and temporary amblyopia, sometimes rising to amaurosis, has been seen and noted by many; both symptoms being clearly due to an insufficient supply of blood to the brain and eye. Black specks, showers of motes, and other photopsiæ are not uncommon. Paresis of one or other of the recti muscles occurs.

Keratitis may also result from exhaustion dependent on prolonged lactation and pregnancy. I saw a woman of worn and pallid aspect who had one child four years of age, another two, and was in the third month of her pregnancy with a third. She suckled the second child thirteen months, and had always dysmenorrhœa when not pregnant. She had keratitis in her right eye, and the vision was reduced to $\frac{1}{100}$; the vision of the left was perfect. The centre of the cornea presented a rough surface caused by the separation of a patch of epithelium. She was ordered meat and quinine, and recovered.

I may also refer to the not infrequent cases of severe keratitis with hypopyon, which are seen as the result of slight scratches of the cornea by the sharp and ragged nails of the infant, which show clearly the great depression of the system, the great relative increase of the white corpuscles, and how much even such dense tissues as the cornea have lost their cohesion and power of resistance to external injurious influences. A further evidence of the same fact is to be found in the predisposition occasioned by lactation to obstruction of the lacrymal ducts and to lacrymal abscess. Many women suffer from obstruction of the ducts of so slight and inoffensive a character that they never think of applying for relief; but when the system is weakened by lactation, either the mucous membrane of the nose or of the nasal duct becomes congested, and complete instead of incomplete obstruction is effected, or possibly the epithelial cells become, owing to their imperfect nutrition, less able to resist the invasion of germs and microbes, and suppuration is established.

I have had one case of detachment of retina, which seemed to me to be directly connected with the exhaustion of the system caused by suckling. Mrs. B——, aged twenty-seven, came to me complaining of complete loss of vision of her left eye. It had begun to fail two months previously, of which she became aware by constantly seeing a cloud of black flies before her. She was a thin, pallid woman, and had just weaned a baby after suckling it for eleven months. Dr. Watts of Charnbrook had instilled a little atropine, and she could then see a little better for a time. The vision of the opposite eye was perfect. Tension of both eyes normal. On examination by means of the ophthalmoscope, it was clear that there was complete detachment of the retina, only a very small portion of the normal red choroid being visible at the lower part of the eye. In this instance a general tonic line of treatment was suggested, but no operative procedure was resorted to.

I have noticed a peculiar affection in women who after severe confinements have made a slow convalescence and have remained for some weeks in the recumbent posture. To beguile the time they have read or worked for many hours in the day, and by looking downward have maintained the inferior recti muscles in strong contraction. Convergent action being also required, the internal recti and the superior oblique muscles are brought into play. The result of this is that, when the patient once more resumes her ordinary duties, she experiences pain in and around the eye, the slightest attempt to read causes discomfort, and she soon applies for relief. As a rule, no changes are visible in the eye on ophthalmoscopic examination. The fundus is healthy, and the retinal vessels and the optic disc perfectly natural. The pain experienced is probably of the nature of spasm, and is best relieved by prolonged rest from work and the use of prisms of 2° or more.

There can be little doubt, I think, that the critical age of the menopause in women has a powerful influence in the development of glaucoma. The age of forty-five to fifty-five is of great frequency in the history of that disease, and it is easy to understand how it may be induced by the more or less sudden arrest of the habitual discharge. Whatever our theories of the etiology of glaucoma may be, it is certain that it is attended with considerable congestion of the choroid and ciliary processes, and with a tendency to the effusion of lymph and the colouring matter of blood into the vitreous, which even in subacute cases may become so cloudy that the details of the fundus cannot be distinguished. In gouty patients the venous system is already distended, but so long as the menstrual discharge continues the vascular fulness undergoes periodical relief and the disease remains in abeyance; as soon as cessation of this function occurs the whole mass of the blood is augmented, and a natural relief is sometimes afforded by diarrhœa, or by hæmorrhage from the nose and other means; but should any circumstance determine the blood to the head, severe headaches are experienced; and if, further, a flow of blood to the eyes is induced by weeping whilst the tone of the vasomotor apparatus is depressed by grief and night-watching, which is often associated with constipation, then an attack of glaucoma is exceedingly likely to supervene, accompanied, in some instances, with intra-ocular hæmorrhage.

At the period of the cessation of the menses, and either directly or indirectly due to it, paresis or paralysis of various nerves and muscles may be observed. Amongst these may be mentioned impairment or loss of the power of accommodation, mydriasis, and strabismus. These conditions, if attended to early, and appropriately treated, are generally only transitory, but if neglected they may become permanent. I have seen several cases where peculiar rolling unsymmetrical movement of one eye occurred when the other was fixed on any object; the two eyes have sometimes been used indifferently, vision being good in both, whilst the other wandered. Women are apt at this time to take but little exercise, to dread cold, and to pursue some perhaps not very prudent plan of treatment. A lady came to me lately who stated that, finding she was becoming stout, she determined to practice Bantingism, and in three months had lost many pounds in weight. The result was that she had become weak and nervous, and had suddenly developed a well-marked convergent squint of one eye. Recovery soon took place on a return to her natural diet, with an allowance of wine and the administration of a little quinine and iron.

In conclusion, then, it may be said that in males the excessive excitement of the sexual organs in youth occasions various subjective symptoms on the side of the eyes—as muscæ, photopsiæ, asthenopia, and loss of accommodation, together with blepharospasm, and at a later period possibly retinitis, retinal hæmorrhages, and white atrophy. That in young women, the epoch of the installation of menstruation may be attended with conjunctivitis, both phlyctenular and follicular, and ulcers of the cornea, with special disposition to the development of keratitis consequent on constitutional taint. That amenorrhœa, especially if suddenly induced, may be followed by hæmorrhage into the anterior chamber or into the vitreous, iritis, irido-choroiditis, optic neuritis, and white atrophy of the optic disc. That dysmenorrhœa may be accompanied by conjunctivitis, keratitis, episcleritis, as well as by inflammation of the uveal tract. That the menopause is often accompanied by effusions into the vitreous and by a disposition to glaucoma; by paresis or paralysis of the ocular muscles. That pregnancy is often attended in the early months with asthenopia, and towards the close with albuminuric retinitis and its consequences—hæmorrhages and white

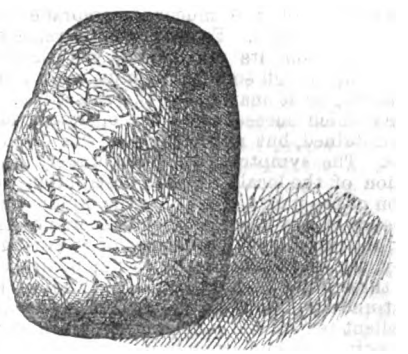
Digitized by Google

patches on the retina; and that if delivery is attended with copious hæmorrhage, loss or great impairment of vision, with white discs, may occur. That in the puerperal state we may meet with embolism, which is sometimes of a septic character, and may rapidly lead to loss of the eye. And, finally, that in lactation—if we may be allowed to include that process in the consideration of the sexual organs—we find asthenopia, great tendency to suppuration of the cornea on slight scratches, and lacrymal diseases to be of common occurrence.

And thus, gentlemen, I have endeavoured to trace with feeble pen and imperfect knowledge some of the relations which exist between the sexual organs and the eye. I have omitted purposely reference to such affections as syphilis, which affect both organs and have an interest peculiarly their own; but I fear I have omitted a multitude of relations that may be familiar to others, and which I can only leave them to supply from their own practice. But I think the facts I have brought forward are sufficiently numerous to show that such a connexion really exists, and that no history of many forms of ophthalmic disease can be regarded as complete which does not include and take into due consideration the conditions of the generative organs.

REPORT OF A

CASE OF OBSTRUCTION OF THE BOWELS.



REMOVAL OF A LARGE IMPACTED GALL-STONE BY OPERATION; RECOVERY.

BY J. FORD ANDERSON, M.D.,
AND
THOMAS SMITH, F.R.C.S.

DR. FORD ANDERSON was sent for on June 30th, 1887, at 4 P.M., to see Mr. D——, a foreign consul, aged sixty-five, and found him suffering from complete obstruction of the bowels, with an anxious expression, fixed pain near the umbilicus, and vomiting. During the visit he vomited a quart of dark fluid, having a distinctly fæcal odour. The pulse was 78, soft; the temperature 98·4°; the urine scanty and high-coloured. The distension of the abdomen was slight, and there was no general tenderness on pressure. Mr. D—— stated that fifteen years previously he had an attack of inflammation of the bowels, which confined him to bed for three months, and ever since that time the motions had not been formed. On one occasion, eighteen months before the present attack, he was under treatment for a few days on account of partial obstruction of the bowels; and since this illness he had kept his motions fluid by means of daily doses of double Carlsbad water. The present illness began on June 26th; since then the obstruction had been complete, and there had been one or two daily attacks of vomiting of offensive fluid. For three days before the 26th he had suffered abdominal pain, and the bowels acted with unusual difficulty. Although feeling very ill, he was unable to lie up, and, among other duties, he attended several official dinners, returning home late in the evenings, which were cold at the time. The last of these dinners was on June 28th, but even on June 30th he went to his office as usual, though he was obliged to return home early and go to bed. Before sending for medical advice he took considerable doses of Carlsbad salts and some castor oil, but without relief.

The treatment consisted in applying warm fomentations to the abdomen, the use of gentle kneading, and in administering frequent enemata of soap-and-water and oil, which were retained in large quantity without distending the rectum, and which came away without any trace of fæces; opiate suppositories and subcutaneous injection of morphia were also given, and on July 2nd and 3rd extract of belladonna in frequent doses of a quarter of a grain was administered. This treatment was followed by relief to the pain. There was, however, occasional vomiting, with the same fæcal smell, but this was less frequent so long as he was fed by the rectum and took nothing by the mouth. Neither flatus nor fæces had passed through the bowel for six days, and, as signs of exhaustion began to appear, it became evident that medical treatment was of no avail. After consultation with Dr. Fenwick and Dr. Habershon operative measures were decided on.

On July 3rd, at 3 P.M., six days after the complete obstruction, the abdomen was opened by Mr. Thomas Smith by a median incision, six inches and a half long, from the umbilicus towards the pubes, the patient being under an anæsthetic administered by Mr. Mills. The small intestine was found much congested, its coats thickened, and moderately distended by flatus. While Dr. Anderson and Dr. Westland kept up equable pressure on the margins of the wound to prevent the escape of the intestines, the small intestine was examined by drawing it across the opening in the abdomen and examining each portion as it appeared. When eight or ten inches had thus been passed through the fingers, a hard mass was discovered in the bowel, on one side of which the intestine was distended and congested, and on the other flaccid and empty. The foreign body gave the sensation of being a gall-stone; it was only slightly movable, and as it could not be squeezed on without danger to the intestine, it was decided to remove it by opening the intestine. The portion of intestine containing the foreign body being drawn out of the abdomen, it was secured above and below by means of clamp forceps shielded with indiarubber tubing drawn over their blades. The intestine was opened by a longitudinal incision, two inches long, opposite the attachment of the mesentery, and the foreign body was removed. The intestinal wound was closed by thirteen sutures inserted after Lembert's method in a double row; they were of fine white silk, which had been thoroughly carbolised. The intestine, after being sutured, was returned to the abdominal cavity. The spray was not used. Every precaution was taken to

The wide end lay uppermost.

render the sponges, instruments, and ligatures aseptic. The external wound was closed by silk sutures, dusted with iodoform externally, and strapped and bandaged. It is quite certain that the entrance of any fluid into the abdominal cavity was completely prevented during the operation, which lasted one hour. The foreign body proved to be a large gall-stone, irregularly cylindrical, or barrel-shaped. The larger or upper end of the stone was smooth, circular, slightly cupped and facetted; the smaller or lower end was more rounded. The colour of the stone was reddish-brown, the two ends being black. The accompanying woodcut gives the exact dimensions of the stone.

Immediately after the operation the patient vomited a quart of the same kind of offensive fluid as had been observed before. He was given a subcutaneous injection of one-third of a grain of morphia.

July 3rd (seven hours after the operation): Pulse 92; temperature 98°. Sickness has ceased. Has had hiccough. Flatus has passed per anum. Restless, but no pain. Urine drawn off. One-third of a grain of morphia injected.—4th: Temperature 99°; pulse 92. Very thirsty. Two liquid actions of the bowels. Abdomen distended by flatus, and relieved by passing enema pipe into the rectum. Had a morphia injection.—5th: Pulse and temperature normal. Passes flatus freely. No pain; no distension. Wound dressed.—6th: Doing well. Two liquid motions passed. Flatus passed freely. Wound dressed; sutures removed.—7th: Two clay-like motions. In every respect doing well.—8th: Restless. Has diarrhœa. Temperature 100° (the highest temperature attained).—9th: much better in every respect.—13th: Bowels acted three times; clay-like motions.

On Aug. 1st the patient resumed, with some precautions, his usual diet, and on the 5th he returned to his office work.

The after-treatment adopted consisted in almost absolute starvation for the first forty-eight hours, and after this

Digitized by Google

nourishment was given by the rectum. Nothing but ice or water in very small quantities was given by the mouth except on the fourth day, when he took a teaspoonful of chicken broth every hour. On the fifth day the same quantity of milk and soda-water was allowed, and the nutrient suppositories and enemata were discontinued, as he had diarrhœa. On the seventh day his diet was improved, and he was allowed beaten-up eggs, broth, milk, jelly, and a little claret. Morphia was used subcutaneously to give sleep and quiet irritability, and opium had to be given by the rectum for his diarrhœa.

The patient has enjoyed better health since the operation than he has done for years. His bowels act in a normal manner, which he believes they have not done for fifteen years, and he has gained in weight.

Remarks.—Although the impacting gall-stone in this case was large, there are many larger on record, which have been either passed per anum, discharged through fistulous openings externally, or found in the intestines after death. The chief interest of the case lies in its successful treatment by surgical operation. It is probably the first case on record of recovery after removal of a gall-stone from the intestine by incision, the intestine being sutured and returned to the peritoneal cavity. It is probable that the so-called "attack of inflammation of the bowels" fifteen years previously marked the time at which the gall-stone gained entrance to the intestine by ulceration, and that from this period there was an ever-increasing obstruction to the passage of fæces, until an attack of intestinal irritation produced sufficient swelling of the mucous membrane to make the obstruction complete. From the appearance of the stone, with a facet on its upper end, we conclude there is still another, though smaller calculus, most probably in the gall bladder, or it may be in the intestines. During the diarrhœa which succeeded to the operation careful watch was maintained, but no concretion was discovered in the motions. The symptoms that fortunately gave a correct indication of the locality of the obstruction were, first, the situation of the pain always near the middle line; secondly, the absence of any considerable distension of the abdomen; thirdly, the very early occurrence of vomiting in the case; fourthly, the scantiness of the urine; fifthly, the fact that two or three pints of fluid could be retained as an enema without unduly distending the rectum. The case furnished an excellent test of the value of Lembert's suture; it kept the intestinal wound, which was two inches in length, satisfactorily closed, although there were six actions of the bowels in the first four days, and on the sixth day there was an attack of diarrhœa. In the after-treatment we adopted a plan of dieting which Mr. Smith had derived from a knowledge of Mr. Lawson Tait's practice in cases of abdominal operation. For forty-eight hours the patient was kept almost entirely without food or fluid of any kind, and although he suffered severely from thirst, yet we believe his recovery without any serious symptoms was largely due to this regimen.

SUPRA-PUBIC LITHOTOMY: A HISTORICAL SKETCH.

By CHARLES W. DULLES, M.D.,

SURGEON TO OUT-PATIENTS IN THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, AND IN THE PENNSYLVANIA HOSPITAL IN PHILADELPHIA.

THE operation of supra-pubic lithotomy was first performed in France in 1551, under the stress of necessity. At this time, Franco, after he had failed to remove a stone from a child of two years, by cutting "on the gripe," made an incision through the abdominal wall and removed the calculus in this way. But he was far from recognising the value of the invention he had been driven to, and did not advise imitation of his example. Nearly thirty years later, Rousset, as a result of studies in regard to Cæsarean section, came to believe that Franco's act of desperation was worthy of deliberate adoption as a method of lithotomy, and, in a work on the Cæsarean operation, described the details he thought advisable, defended the theoretic merits of the method, and answered objections he supposed might be raised—objections which, in fact, were afterwards raised. Rousset never had the opportunity to perform the operation, the death of Henry III. depriving him of the hope of obtaining permission to practise it upon a criminal—a favourite way of experimenting in those days. Nevertheless, to Rousset, and Rousset alone, belongs the credit of first seriously advocating the removal of stone from the bladder by incision above the pubes. Franco's act was unpremeditated, and the value of its results unrecognised by him. Rousset saw what good use it might be turned to, and his name should never be left out of any account of supra-pubic lithotomy. Early in the seventeenth century Fabricius Hildanus did this operation, but strongly dissuaded others from attempting it. Nevertheless, contemporary writings would indicate that it continued in use in France much oftener that can be established from recorded cases.

It was not till near 1700 that the operation seems to have crossed the British Channel, the first recorded operation on the western side being done by Proby, in Edinburgh, to remove from a woman's bladder an ivory bodkin which she declared she had swallowed by accident. In 1718 the method was demonstrated by James Douglas before the Royal Society of London. The next year his brother, John Douglas, performed it successfully, and in 1820 he published a work upon it, called "Lithotomia Douglasiana." Deschamps accuses him openly of having borrowed his idea from Rousset's book, which both the brothers denied that he had ever seen. However this may be, the operation at once secured adherents, and was employed by a number of English surgeons both in hospitals and in private practice. The most noted operator at that time was Cheselden, the perfector of the left lateral operation, often called by his name. He followed Douglas's method in ten cases. All of his patients recovered except one, who died of diarrhœa and fever due to an indiscretion after he was able to go about. Cheselden finally abandoned this method because others cut the peritoneum and burst the bladder in attempting to distend it. Other operators in England did the supra-pubic operation about this time; so that for a while it seemed to have more acceptance here than in the land of its origin. In Holland it was employed by Sermes at least sixteen times, in five of which death followed, and the authorities forbade his using it any more.

In 1758, the scene of greatest activity was transferred to France, through the energy and success of Frère Côsme, who did a hundred operations of this kind from 1758 to 1781, and lost but nineteen of his patients. Côsme first used a counter-opening through the perineum to secure drainage, though this was first suggested by Palluci in 1750, together with a recommendation to close the wound with sutures. Côsme, however, has undisputed claims to the invention of the *sonde-à-dard*. Scarcely had Côsme left the world when Souberbielle began a series of operations in 1796, which, continuing until 1843, when the operator was eighty-eight years old, numbered in all 115. Thus we see that two French surgeons have contributed 215, or about one-third of all the cases recorded up to 1881.

With the early part of the present century the well-known names of Scarpa, Vacca Berlinghieri, Dupuytren, Home, Dzondi, Amussat, Lisfranc, and Civiale, in Europe, and of Gibson, Carpenter, and McClellan in America, enter the list of those who used the supra-pubic operation. All, however, practised it without preference, if Amussat be excepted. The prevailing opinion had come to be adverse to this operation, its dangers being exaggerated and the safety of perineal lithotomy being considered all that could be expected. One author copied another in condemning it, and it looked as as though it might soon fall into oblivion. In 1856 Dr. G. Murray Humphry, of Cambridge, England, published an account of a successful operation done by him in 1848, together with a table of 104 cases, which has been the basis of most English statistical estimates until after 1875. This collation of statistics was not calculated to give any great confidence in the supra-pubic method, and the English opinion has continued until recently to be in the main unfavourable to it.

In Germany, on the other hand, there began, at about the same time, a decided revival of interest in this operation. This was principally attributable to the influence of Prof. Günther, of Leipsic, who collected 260 cases and printed their details in an able monograph entitled "Der hohe Steinschnitt seit seinem Ursprunge bis zu seiner jetzigen Ausbildung" (Leipzig, 1851). His presentation of the subject, backed by his own successful employment of it, caused the opinions of his countrymen to be more favourable than those of any other nationality, while in Austria and Holland his

Digitized by Google

influence has also been marked. Strange to say, there is scarcely an allusion to this, the best monograph ever published on this subject, by any English or American author before 1875, up to which time every one of these authors referred to Humphry's table for their estimate of the merits of supra-pubic lithotomy. In England and America the operation was but rarely done and hardly ever heard of. Here, however, occasionally a surgeon was driven to it because of failure to extract a stone through the perineum. From 1853 to 1857, Dr. Willard Parker, of New York, influenced by German teachings, cut four women and one man in this way, and then gave the method up. The late Dr. Krackowitzer, of New York, whose name betrays his nationality, wrote me in 1874 that he had done this operation six times since 1859. Dr. Guido Bell, of Indianapolis, a German, has done it four times since 1867 without a death. Dr. Jacobi, of New York, another German it will be observed, has done it seven times since 1868. But with these exceptions the operations of no surgeon in America had, before 1875, exceeded two or three in number.

In 1874, I was one day present at an operation of lithotomy in which several skillful surgeons laboured long and hard to extract a calculus by the usual lateral operation of Cheselden. Three hours were occupied in fruitless attempts to remove the stone entire, or to crush it. At the end of this time it was suggested to try the "high operation" before giving the attempt up. No one present had ever seen this method practised; but the operator, being a good anatomist, had no difficulty in carrying it out; and in about three minutes the bladder had been opened above the pubes, the stone—which was as large as a pullet's egg—had been easily removed, a few stitches had been inserted, and the patient was taken back to his bed. The sight of this operation led me—then a student of medicine—to a study of the history and merits of the supra-pubic operation of lithotomy, which covered a period of a year, and led to the publication of a paper on the subject, which was printed in the *American Journal of the Medical Sciences*, July, 1875. In this paper there is an abstract of the contents of an inaugural thesis, which embraced a historical sketch of the "high operation" from the days of Franco to 1875, and an analysis of the facts gathered from a table of statistics containing reports of 478 cases. The analysis showed the results of supra-pubic lithotomy, by themselves and compared with those of the lateral (perineal) operation. One of the most interesting features of the analysis was the demonstration of the fact that supra-pubic lithotomy gives as good results as lateral lithotomy for calculi weighing between one and two ounces, and better results for calculi above two ounces in weight. Upon theoretical grounds, it was contended in this paper that the supra-pubic operation is preferable to the lateral; and it was asked: "If these, then, be the facts, is not this method deserving of more attention and a fairer trial than it has yet had? Does it not, theoretically and by its actual results, commend itself to the candid judgment as a method which offers sufficient probability of success, if rightly and carefully executed, to lead to its application in other cases than the most desperate? For many years it has been assigned this position of a 'forlorn hope.' Shall it not be some day placed where, with less disastrous obstacles, it may win success without having its victories made to seem like defeats because of the losses rendered inevitable by the field to which it has been limited?".

From the time when this hope was expressed until the present, I have not ceased to follow with deep interest the history of supra-pubic lithotomy. For some years I continued to collate and analyse its statistics, so that, in 1881, I had collected and studied the reports of 636 operations by this method, with results practically identical with those published in 1875. Especially gratifying was it to one who had faith in the merits of supra-pubic lithotomy to note how it was gaining the confidence of surgeons all over the world, so that the operation was coming into more and more general use. A study of its history by epochs shows that it was practised in the sixteenth century only once; in the seventeenth only seven times; in the eighteenth 191 times; in the first half of the nineteenth 237 times; and in the next thirty years more than 200 times. At this time (1887) the whole surgical world seems convinced of the merits and practicability of this method. This state of affairs can be traced to several things: one, the steady defence of the method by those who believed in it; another, the demonstration of its merits by the study of a sufficiently large number of cases; another—and most important factor—the proposition of Professor Petersen to facilitate access to the bladder by distension of the rectum;[1] another, the zeal with which it has been championed and practised lately in Paris by Monod, Guyon, Perier, and other surgeons; and, lastly, the conversion of Sir Henry Thompson, who, after long denying its claims, has become one of its most enthusiastic propagandists. At the present day, then, supra-pubic lithotomy may be said to be on the very crest of the wave of popularity. It is even necessary, I think, for those who have believed most patiently and consistently in its merits, to raise a voice of caution, lest it suffer by being overrated, even as it so long suffered by being underrated. After thirteen years of study of this method and an analysis of over 700 operations, I have come to the conclusion that a temperate view of the subject will lead to the conviction that the supra-pubic operation deserves to rank above all other methods of lithotomy for stones of large size, and that its applicability to any case should be carefully discussed before deciding to cut through the perineum.

Chronological Summary.—1551: Franco did the first operation. 1580: Rousset described and advocated it. 1694: Proby did the operation successfully. 1698: Solengius distended the bladder with air. 1719: Douglas established it in England; Bamber injected the bladder after opening the abdomen. 1724: Sermes made a cut in the perineum to introduce the sound. 1739: Clelland proposed a peculiar sound. 1750: Pallucci proposed a perineal incision for drainage, and suture of abdominal wound. 1758: Côsme used the sonde-á-dard and perineal counter-incision; he also attempted suture of the wound. 1773: Le Blanc said to have operated "*en deux temps.*" 1783: Aitken proposed dividing the "share-bones." 1785: Espiaud placed his patient in a sitting posture after operation. 1800: Souberbielle argued that the catheter was not indispensable for drainage. 1826: Pinel Grandchamp proposed suture of the bladder-wound. 1828: Baudens operated with bladder undistended. 1829: Tanchou practised constant irrigation of bladder and wound. Geo. Bell dilated a fistula to remove a stone, and proposed this as a method. 1832: Vidal de Cassis proposed the method "*en deux temps.*" 1841: Nélaton did first operation "*en deux temps.*" 1843: Felpetu opposed using sutures. 1850: Delery applied sulphate of iron and powdered camphor to wound to prevent septic absorption. 1851: Günther published his monograph. 1854: Baudens sewed up bladder after extraction of bullet. 1857: Bruns practised suture of the bladder wound. 1871: Listerism used by Lister. 1874: Anger recommended use of thermo-cautery. 1875: Trendelenburg proposed placing patient on abdomen for drainage. Dulles reported analysis of 478 cases, and advocated general adoption. 1879; Flury published statistics of ninety-three cases. Van Geodœver advocated general adoption. 1880: Petersen recommended distension of the rectum to raise distended bladder out of pelvis. 1881: Langenbuch proposed "*sectio alta plastica.*"

ON ECZEMA AND PSORIASIS.

BY A. S. MYRTLE, M.D. EDIN.

FORTY years' experience with any class of patients should afford many and valuable opportunities of comparative observation, not only as to the results of one's own practice, but as regards that of many of the most distinguished of the profession. Such has been my lot; and it is after having treated thousands of cases of eczema and psoriasis—cases, many of them at least, which had been seen by the best specialists,—tried every remedy, from Holloway's ointment to cuticura, and visited the most famous watering places in Europe, without securing much benefit, that I venture to lay the lessons I have been taught and the conclusions I have arrived at before the readers of THE LANCET. I shall assume that they are all as familiar with the symptoms and varieties of both affections as I am. As far as varieties go, I may at once say I recognise only eczema and psoriasis; the forms they take are practically of no importance, however imposing they look on paper. Everyone will admit that both are becoming more and more common: as a proof of this I need only point to the rapid growth of dermato-

[1] This plan may have been suggested by the experiments of Dr. Garson, of Edinburgh, which were reported to the Congress of German Surgeons by Prof. Braune.

Digitized by Google

logists. In 1845, in England, we had only one of any note, Erasmus Wilson; Scotland was entirely without; and Ireland was little better off. Now we have them flourishing in every city, and attached to every general hospital in the kingdom. The etiology of both affections is still to be discovered, notwithstanding the great advances made in every department of pathology and therapeutics. As yet no bacillus has been found, and, what is more, I prophesy that none ever will be; for wherever that most fashionable, highly cultivated micro-organism takes possession, death and destruction follow. Look at splenic fever, chicken cholera, and tubercle. Now, the affections under our consideration are in reality scarcely to be classed as diseases, for, correctly speaking, they are mere divergences or exaggerations of that cell life continually going on in health, and, however extensive, vexatious, and protracted, they never lead to any structural changes or permanent functional derangements, and never destroy life. Whilst our knowledge as to their proximate cause has made no progress, I am pleased to add that the same cannot be said as to their treatment, for here we have made immense strides; still, it is emphatically experimental, quite as empirical to-day as it was when I commenced practice. We have no royal road to cure—no specific; the best methods of treatment, the most usually successful every now and again, even in the same individual, prove worse than useless. Often have I fancied I had made a great discovery, thought of the Patent Office and enormous wealth, but, like Sir Andrew Clark and cocaine in summer catarrh, my hopes have been rudely shaken. Patients and friends continually ask, "Can you cure this? Will it ever return?" I answer to both questions, "Yes." Some also ask, "Would it not be dangerous to drive this in?" And even medical men, I suppose by way of comforting the patient, say, "It is better out." My great aim is to cure, and as quickly as possible, with one solitary exception—eczema capitis in teething infants.

It has become the fashion to say that both eczema and psoriasis are manifestations of gout, and that if you wish to succeed in treating them you must do so "according to the well-known therapeutic indications observed in that condition." These are the words of a Dublin physician. I hold that they have no more to do with gout than tapeworm has; but, like every other aberration of health, when they occur in a gouty subject they are all the more difficult of cure. I shall mention one reason only against the gouty theory of causation. Wherever any tissue has been the frequent seat of gout, and if to periodic we add protracted, structural changes invariably follow—degenerations, in fact,—and the part so affected never regains its normal condition. What happens here? I can produce cases that have been subject to attacks of both for thirty—ay, fifty—years, who will tell you that every portion of their skins has been, not once, but scores of times, the seat of these eruptions, and if you examine any part where they no longer exist you will find it perfectly healthy in appearance, and as capable of performing its functions as if these had never been interfered with. Would such be the case were gout the cause? Hereditary transmission affords no explanation of their etiology. Everything is hereditary—moral, mental, and physical; and, in my opinion, it is a waste of words to say that any disease is hereditary when we know it must be. Besides, whether hereditary or acquired, it makes no difference in prognosis or treatment. In both, what we do know is this, that there is an abnormal activity in cell life, and that this cell proliferation is due to fitful nerve disturbances—vaso-motor possibly, central frequently. How common is it to find a burst of one or the other follow close on the heels of grief, worry, overstrain of mind or body. In eczema we frequently observe the influence which digestion and assimilation exert on its behaviour, and, above all, the way in which hepatic conditions, whether functional or organic, interfere with the eczematous. Consequently, we must recognise the necessity of attention to diet and internal treatment. In psoriasis we seldom find any such influences at work. I am not aware that it is in any way affected by diet, or that it can be produced by any amount of dirt. As a rule, the subject of it is in rude health, capable in every sense of the word, and, with the exception of arsenic, little affected by internal remedies. I hold that both are non-contagious, and I differ entirely with Dr. Jonathan Hutchinson in his recently expressed views that the spread of eczema and psoriasis to contiguous portions of skin is due to "an infective process," and that this must serve as "the keynote of a large part of the therapeutics of the skin." By an infective process I mean, and I suppose Dr. J. Hutchinson means, the transmission of a noxious principle or material from one individual to another, or from one portion of the same individual to another portion. If eczema and psoriasis are spread by infection, surely we might look for their being frequently given to the friends and attendants constantly employed in dressing and waiting on those suffering from the very worst forms of both; in all my experience I have never met with such a result. If they spread by an infective process, why not chilblains, which, according to the same authority, arise from "inherited peculiarity of tissue as regards susceptibility to cold"—in fact, vaso-motor disturbance. This infective process is a new doctrine, and we are entitled to ask what is the contagium, and how does it happen that a single patch of eczema lasts a lifetime without spreading? Common sense and long experience tell me that the common cause of the spread of eczema is scratching, and wherever this is resorted to self-aggravation is the law, but that aggravation is not brought about by infection either in the part or through the blood, *but* by the nails; in fact, I go so far as to say—if you prevent itching, you do away with scratching, and the eczema is cured.

I shall not take up time by dwelling on ordinary cases of eczema or psoriasis. These can be successfully dealt with anywhere and by anyone qualified. I shall confine myself to three extraordinary cases of each, cases that had defied all treatment. Everyone is familiar with the popular belief that natural sulphur waters have great power as therapeutic agents in all chronic cutaneous diseases. Medical men recognise this fact, and send hundreds of patients to the sulphurous springs of Moffat, Strathpeffer, and Harrogate, as well as Aix-les-Bains, Aix-la-Chapelle, and other continental spas, to undergo the "cure," as it is called. Now, I shall briefly sketch how these same cases do at Harrogate.

Mr. Edmund Furner of Brighton, in 1860, sent me a retired Indian judge, aged seventy, who had been a martyr to one of the worse forms of eczema I ever saw. From head to foot there was scarcely a morsel of skin free from it; some parts were raw, exuding serum and pus, encrusted with scabs, on removal of which angry sores were exposed. He had visited Wiesbaden, Homburg, Aix-la-Chapelle, and Cauterets. He brought a note in which Mr. Furner stated it was the decided opinion of Erasmus Wilson, two eminent London physicians, and himself that no attempt must be made to cure the skin, as they believed that would kill the patient. I did nothing, but left him to swelter in Wilson's benzoated zinc ointment; in three months he went home as he came. Here I may observe that all ointments in such a condition are filthy and injurious; they rapidly undergo chemical changes, and add to the irritation. Next year, to my sorrow, the patient returned as bad as ever. One night I called on him accidentally. I found him in great trouble, talking of doing away with himself; he longed for death. Then I told him it was thought if his skin were cured he would die from lung mischief, but if he liked I would try to cure him. He agreed. Next morning he had his first alkaline sulphur bath, at 98°, for six minutes; this removed all ointment. He was dried carefully, and, as his skin was raw and bleeding, I covered the whole with fine sheet cotton-wool medicated with a preparation of coal-tar. Each day his stay in the bath was prolonged, and the dressing repeated. In six weeks he was cured. No lung mischief appeared, and he died at eighty of decay, never having suffered to any extent from eczema again.

Strangely enough, the next very bad case was a gentleman who had also been a judge in Calcutta for many years, and had to resign his appointment on account of eczema. He had gone to one health resort after another, had consulted the best authorities at home and abroad, and, hearing of Dr. McCall Anderson, he went to Glasgow. Dr. Anderson sent him to me for the purpose of drinking and bathing in our sulphur waters. His body was in such a state that he could not wear his usual clothes or lie down in bed; he sat wrapped in thin muslin, with a loose skirt and dressing-gown. He was flayed in many parts, and the raw surfaces were the seat of serous and purulent discharges to a painful and exhaustive degree. I resorted to the same treatment as in the former case, dressing him myself daily; the wool stuck to him at first, and had to be rudely torn off. The result was that in three weeks he could bear his clothes, and in six he left with a sound skin. I have seen him often since, and he has never had more than a slight threatening of his old enemy.

Digitized by Google

Last April Mr. J——, a surgeon in large practice, placed himself under my care. His history was a sad one: from his ninth year he had been a martyr to eczema; twice he was cured—once by an attack of acute pneumonia, and again by an attack of rheumatic spinal meningitis,—but with returning strength the eruption returned. In 1885 he never passed a night free from urticaria, and since then his hands, soles of feet, elbows, buttocks, scrotum, and thighs were so involved with eczema that he was entirely crippled, and had to give up practice in the beginning of this year. Every kind of treatment, internal and external, had been tried—arsenic, iron, iodide of potassium, alkalies, and acids. I put him under a course of our sulphur waters and baths, and in a week he was greatly better, and at the end of the third week he was so comfortable and presentable that he went home and resumed work. About four weeks ago he wrote to me; he was able to keep the eruption quiet by using an ointment with carbolic acid, nitrate of mercury, bismuth, and lard. Unfortunately about a week after that he read Dr. Crocker's account of his success in eczema by counter-irritation. Mr. J—— jumped at the idea, and at once applied a mustard plaster to his nape. Suddenly, as he calls it, all the old places were recrudescent, his face became covered with blotches, and his body was in a blaze; he wrote to me in despair. With all deference to Dr. Crocker, and whilst concurring in his views as to the influence the vaso-motors have in eczema, I cannot speak too strongly against the application of counter-irritants to the skin of the eczematous for any purpose whatever. I have brought the case forward because, although only half cured, that proved an immense boon, and had Mr. J—— been able to stay for six weeks instead of three, I feel almost certain the result would have been most satisfactory.

Captain M—— was obliged to resign his commission in the army on account of a severe and very general attack of psoriasis, which made its appearance shortly after he joined his regiment in India. For eleven years he had never been free from it. Of course, he had done everything he could to get rid of it, and tried every remedy and baths. When I saw him his whole body was covered with scales, varying in size from a shilling to a pin's head. His extremities and face were also in the same plight, and his nails were thickened and corrugated. I found that all his organs were healthly and functions natural. I ordered him a mild sulphur bath at as low a temperature as he could bear, and to remain in it as long as he could without feeling chilled. For three months he lay in his bath sometimes for an hour, and at most for an hour and a quarter. At the end of this course every patch had disappeared, and, except for his nails, it could not be recognised that he had suffered from psoriasis. He went to Paris, and in the following spring announced the fact that his nails were nearly well, and that he was going to marry. I have never heard of him since.

Dr. Holman of Reigate sent me a gentleman with very bad psoriasis last year. He had suffered from it for a long time, and had large patches on his body, forehead, face, arms, and hands. A three weeks' course of waters and baths cleared him. He returned last April with a very good report, and underwent a fortnight's treatment by way of prevention.

A month ago Dr. Holman of Hampstead sent me a youth of nineteen who had never in his recollection been free from psoriasis. His face and neck were covered, giving him a most unsightly appearance; large patches running into each other were on the body, and on the legs and arms were a number of rings, more or less regular. He took a full course of sulphur and chalybeate water internally. He remained in as cold a sulphur bath as could be borne for an hour each day, and the result is his face and neck are entirely well, and the other patches have nearly disappeared.

Before 1876 I invariably ordered baths at a temperature of from 96·8° to 104°, and, finding that little impression was made on the eruption, I lowered the temperature until I got my patients into a cool bath, and I found a marked diminution of cell activity, and the longer I could keep them under this the greater and more rapid was the improvement. Certain conditions are absolutely necessary for such strong measures; the patient must be sound in all his organs. Were anyone with disease of the heart, liver, or kidney subjected to such a severe ordeal, most serious mischief might result; so also with those predisposed to gout and rheumatism.

In psoriasis, dieting is of no importance, and internal remedies are of as little. The same cannot be said of eczema; but in both I trust greatly to external applications. As a preventive against recurrent attacks of eczema dermato-therapeutic quinine lotion is by far the best thing I have yet hit upon. It acts as a powerful tonic as well as a sedative, and can be applied with freedom to all parts, as it never produces the slightest irritation. Such preparations are greatly to be preferred to ointments and pigments, which always rub off and soil whatever they come in contact with. I frequently paint old-standing patches of psoriasis and eczema with naphthaline tincture, after immersion in the sulphur bath, with the most satisfactory results, and confidently recommend a trial of it after other applications have failed.

Harrogate.

SOME CURIOUS VASO-MOTOR PHENOMENA OF TYPHOID FEVER.

BY ANGEL MONEY, M.D.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN.

I DESIRE to publish some fragmentary clinical observations on certain so-called vaso-motor phenomena which may be observed in some continued fevers. If these phenomena have been previously observed, they have at least failed to obtain the recognition their interest and perhaps importance merits; and such mention as is accorded them by systematic writers is so unsatisfactory, not to say desultory, that it is plain the presence or existence of such phenomena did not appear to authors to have any definite value beyond that which attaches to mere ordinary phenomena. Nor, indeed, although I make more of them, and perceive in them a significance which may prove of diagnostic and even prognostic importance, do I pretend yet to have reached the bottom of their powers; and although I feel sure they have a worth, I cannot yet, even approximately, state what that worth may be, either intrinsically or extrinsically. But these are no reasons why I should not state what I have seen and set forth what I think.

In many cases of typhoid and rheumatic fever curious vaso-motor phenomena may be detected in the skin, and, after considerable observation, I think most of them may be grouped in one or other of the following classes:—In the first class I may place the *spontaneous vaso-motor phenomena*, by which I mean those facts which may be witnessed without further irritation or stimulation than attends the mere exposure of a surface of the body or limb on which the observation may be made. If it be the surface of the abdomen, this may be found to be for the most part of a pinkish hue, such as tends to obscure the presence of rose spots, if such be present; but scattered here and there through the red tint, which they mottle, may be seen areas of whiteness, which present a distinct and striking contrast with the general tint, and are, moreover, characterised by varying in distinctness, being whiter or less white at one moment than at the preceding or succeeding moment. If to such a skin, under such circumstances, the additional condition be added of a slight mechanical—and, I may add, electrical or thermal—stimulation, certain further observations may be made, the purport of which I cannot pretend to fathom, though it would be easy to offer plenty of hypothetical explanations. It generally happens that the stimulated area or line turns white or ivory-tinted after the lapse of a rather long latent period, variable in different cases and at different times for unascertained reasons, and measurable generally by seconds. The whiteness is not strictly limited to the irritated section, but spreads away from the part stimulated, and in a gradual, decreasing fashion. Moreover, the pallor does not appear abruptly after the period of latency, but the pinkness of the skin gradually gives way to the whiteness, and the changing hue is very perceptible. Thus, both in space and time the phenomenon has a graduation and a duration which are, comparatively speaking, of slow course, and remind one rather of the contraction of smooth, plain, nerveless muscular fibre, than the rapid, sharp contractions of the well-nerved voluntary muscle. And although too much stress should not be laid on this feature, still I cannot but think

Digitized by Google

that these characters suggest the independence of the phenomena on the nervous system, and their dependence on the mere living undifferentiated protoplasm of the walls of the capillary vessels. But I am not bigoted in the matter of explanations of phenomena, and care more for the accuracy of observations and for the determination of facts.

I want further opportunities for examining the various etiological factors which must concur and the different conditional causes which must be absent for the development of this phenomenon. I make no doubt in my own mind from general grounds of causation, that one chief agent or agency must be at work in the production of the phenomenon, but, nevertheless, all that we yet know of etiology, whether of disease or of other earthly processes, points conclusively to the belief that many other conditions besides the chief one—the exciting cause as we call it—must be operative, and some conditions not operative, in the causation of the process. I have a few other facts of special connexion with the present phenomenon. Frequently, but not always, it will be found that exposure of the skin of the arm and forearm in the same subject presents a contrast with the previously or simultaneously exposed surface of the abdomen, the general tint being white with irregular patches, sometimes streaks, of pink or darker red. When this contrast is evident, and occasionally when there is no such general and spontaneous dissimilarity of appearance, mechanical, and sometimes (? always) electrical and thermic, irritation of the skin of the arm will be followed after a similar, but perhaps generally a trifle shorter, period of latency by the gradual development of the *tache cérébrale* or red streak, having the usual characters of that phenomenon. Sometimes the surface of the arm has a general pink tint on first exposing it to the atmosphere, and this may rapidly change to white, but the colour of the written characters thereon may be deep red. The contrast in colour may be still more remarkable, even in the same case; the writing may be white on the surface of the abdomen, red on the forearm, white on the legs. I do lay considerable stress on the circumstance that the temperature of the skin and of the body is usually high in cases which present these vascular phenomena, and, further, I have most generally observed them in full perfection when the skin has not been perceptibly sweating. But, as proving that neither increased heat nor an especial dryness of the cutaneous tissues is necessary to the production of such phenomena, I may observe that I have seen them very well marked in cases of epilepsy and chorea of uncomplicated and afebrile sort. It may be worth placing on record also in this connexion that the majority of cases in which these observations were made the brain was certainly perturbed in its functions, for delirium was frequently present at some period of the twenty-four hours, mostly at night-time; still I must add that my observations were usually made during the day-time, and when the intellect of the patient, to all ordinary modes of investigation, did not seem to be abnormally affected. I should like to make more investigations at different hours of the day in order to ascertain whether there are any daily or other periodic variations in the phenomena, and also to determine whether the morbid signs present any concomitant variations with other corporeal phenomena, either normal or abnormal. I do not think that a careful clinical study of this nature would be either a waste of time or would not be of some clinical avail.

Harley-street, W.

GLASGOW WESTERN INFIRMARY. — At the annual meeting of this institution, held a few days ago, the report submitted showed that 14,661 out-door patients had been treated during the year, and 3928 in-door. Of these latter 277 died, giving a percentage mortality of 7·7; but of the fatal cases 44 were hopeless when admitted, reducing the death-rate to 6·6 per cent. The average residence of each patient was 37·2 days. The cost of each bed fully occupied during the year was £49 0*s.* 3½*d.*; the average cost per patient was £4 19*s.* 10*d.* Financially the infirmary was reported to be in a flourishing condition, a balance of £9000 being carried forward to next year.

THE Blair Convalescent Hospital, which has been erected as a result of the munificence of the late Stephen Blair, formerly M.P. for Bolton, at Bromley Cross, near Bolton, is now practically completed, and will shortly be opened for the free admission of convalescents "without limit of domicile."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

MULTIPLE MINUTE ULCERS OF THE CORNEÆ FOLLOWING EXPOSURE TO ELECTRIC LIGHT.

BY T. PHILLIPS,
CLINICAL ASSISTANT, MOORFIELDS EYE HOSPITAL.

IN this case the causal relations between the exposure to the electric light and the lesions of the corneæ seem to be fairly complete.

On August 31st an electrician, aged twenty-four years, while engaged in making observations of a very powerful electric arc, removed the usual protection in order to make a "better examination," thus exposing his eyes for about four minutes to the action of the light. He suffered no immediate inconvenience; resumed the shade, continued his labours for a short time, went home, had a "good sleep," and had no cause for complaint until he awoke about four hours after the exposure. He then suffered from acute pain in and about the eyes, great intolerance of light, and was unable to sleep. He said, "I was stone blind."

I saw the patient on September 5th. He was still suffering from acute pain and intense photophobia, which prevented examination till the application of a 10 per cent. solution of cocaine. The anterior surfaces of both corneæ were affected. The right was dotted all over with small definite ulcers. The left had six such ulcers arranged in pairs of three rows disposed vertically. The appearance of these ulcers was similar to that presented by the corneal ulceration which occurs in states of perverted innervation of the eye. The ophthalmoscope revealed nothing abnormal.

The eyes were bathed with boric acid lotion, and a solution of cocaine and atropine applied night and morning. In the meantime both eyes were closed with pads smeared with boric acid ointment.

Professor Tweedy kindly saw the case a few days afterwards, and verified the above description and approved the treatment. He also said that he had seen several cases of conjunctivitis with photophobia following exposure to a naked electric light, but had not noticed the corneal ulceration before.

The patient was well in about a fortnight.

A very interesting question suggested by the case is the possible cause of the phenomena—whether (*a*) due to direct damage of the corneal structure, (*b*) to direct damage to the trophic nerves, or (*c*) to indirect damage to the trophic nerves reflexly induced through the optic nerve. It should perhaps be stated that there was no past history of eye disease, except a trifling injury, and the vision was previously normal.

ABSENCE OF THE OCCIPITAL BONE IN NEWLY BORN INFANTS.

BY W. C. BROWN, M.D.

The publication of an instance of this rare deformity in THE LANCET of June 11th, has induced me to give particulars of two cases that have recently occurred in my practice.

On April 26th, 1886, I was called to attend Mrs. N—, aged twenty-four, in her first confinement. She complained of having been suffering from extremely strong fœtal movements for a day or two. On examination I found the os dilated, the head well down, and the face presenting. Anticipating a tedious confinement, I was surprised at the ease and rapidity of delivery. On the birth of the infant the reason of this was made apparent; the back of the cranium had remained completely undeveloped. A large soft tumour containing the cerebellum and part of the cerebrum protruded, and on running the finger round its edge the parietal bones could be felt soft and gelatinous. The arches of several of the cervical vertebræ were also wanting, the tumour extending down the back of the neck for some distance. Unlike Dr. Fraser's case, the skin was quite intact over the tumour, and a considerable quantity of hair was growing on it. The child, a healthy

Digitized by Google

and well-nourished female of full term, drew a few respirations after its birth, but did not live for five minutes. The mother made a good recovery, and I saw nothing more of her until two months ago, when she came to tell me that she was again pregnant, and that she expected to be confined about the beginning of September. I was called to attend her, however, on July 7th, and found her well advanced in labour, with a foot presenting. There was a very large quantity of liquor amnii, but delivery was rapid and easy. On examining the fœtus, an eight-months' still-born female, exactly the same deformity was found to exist. The tumour was, however, not so large, and the arches of the cervical vertebræ were in this instance complete. In every other respect the deformity was identical with that of the first child. Notwithstanding the fact that the fœtus had not respired, pressure on the tumour caused convulsions, and, if maintained for some time, severe tetanic spasms. In each instance there was a peculiar protrusion of the eyes, which, I observe, is noted also by Dr. Fraser, and the neck was extremely short. In each instance, also, the skin over the tumour was so loose that the finger could easily be pushed between the cerebellum and the medulla, and also for some distance down the spinal canal. The occipital bone—in fact, the entire bony arch behind the foramen magnum—did not exist even in the most rudimentary condition, and the skin was lying directly on the membranes of the brain.

This arrest of development of the posterior arch of the skull is evidently caused by the primitive vertebral discs at the upper extremity of the fœtal chorda dorsalis being too few. If the number be even one too few, it will easily be seen how a gap may be left. The double curvature forward of the cerebral extremity, which takes place about the seventh week, would tend to pull what vertebral discs there are forward to the anterior part of the skull. In this way a deficiency in number of the vertebral discs results in a gap being left at the back part of the skull, and the posterior cerebral vesicles are left with no vertebral disc to mould itself over them into a bony covering. From the strong fœtal movements that had been felt in both labours I concluded that intra-uterine convulsions had supervened a certain stage of development, and that this had terminated the pregnancy. The parents are both young and healthy Europeans, the father being of German, the mother of English birth. I have been able to assign no cause for both of their offspring being born with this rare and peculiar malformation.

Penang.

THE TREATMENT OF COMA IN YOUNG CHILDREN BY HYPODERMIC INJECTION.

By F. R. HUMPHREYS, L.R.C.P. LOND., &c.

THE following cases may be of interest, as they seem to indicate a line of treatment applicable even *in extremis*.

CASE 1.—An infant aged ten months, very ill for fourteen days with broncho-pneumonia, complicated by relapses. When first seen (3.40 A.M.) the child was deeply unconscious, unable to swallow, the lips blue, and dying; it had been in this condition for two hours previous to my being sent for. The condition had come on very gradually.—3.40 A.M.: Pulse 176; respiration 96. Three minims of brandy were injected hypodermically.—3.45 A.M.: The brandy injection was repeated. The mouth was noticed to be drawn down to the right.—4.5 A.M.: Pulse 168; respiration 92. Better; coughed a little; nystagmus. Hypodermic injection of $\frac{1}{120}$th of a grain of digitalin. The child opened its eyes, looked about, and was able to swallow a little.—4.30 A.M.: Pulse 168; respiration 86. The child had improved so much that I left. It died at 9 A.M. I was told it gradually relapsed into its former state. I was only called in in the absence of the doctor in attendance. On making a hurried physical examination, the right lung appeared nearly solid, and the left was badly affected.

CASE 2.—A boy aged nine months, suffering from measles (fifth day). The rash had gone a few hours before. Hyperpyrexia with consolidation of the left lung having set in, the doctor who was in attendance declared the case hopeless, and said he would not come again. I was therefore asked to see what I could do. When first seen the child had just had a convulsion, but I was told it had been unconscious for some hours. The lips were blue, the pupils extremely contracted, and I could get no reaction to any stimulus.—3.30 P.M.: Respiration 12; temperature 104·8°. It was wrapped in a wet sheet, an enema of brandy, egg, and milk administered, and a hypodermic injection of two minims of brandy given.—4.50 P.M.: Respiration 22; temperature 102·7°; pulse 140. The child was breathing better, and appeared improving. During this period six minims of brandy and $\frac{1}{60}$th of a grain of digitalin were separately injected under the skin.—7.30 P.M.: Temperature normal; much better; able to swallow. The consolidation cleared up; but meningitis set in, and the child died from exhaustion on the seventh day after I first saw him. Each time he flagged brandy or digitalin was administered hypodermically, and each time there was temporary improvement. The child was unhealthy, living under bad hygienic circumstances, in great part nursed by a mother who was absolutely ignorant of such work, and it was only after repeated relapses that it finally succumbed.

In an extremely similar case to the last, broncho-pneumonia passing on to meningitis, with hyperpyrexia (107°), occurred in an elderly but healthy man, and death ensued in a few hours. Hypodermic injection was not made use of, and sponging was of no avail.

Queen's-crescent, N.W.

COMPOUND DISLOCATION OF THE PROXIMAL END OF THE MIDDLE METACARPAL BONE FROM THE OS MAGNUM.

By ERNEST CUSSE, M.R.C.S., &c.

THIS case being an instance of a rare injury may be worthy of note.

J. E——, a gardener, fell from a tree some twelve feet on to the palm of his left hand. On presenting himself at the Bournemouth Dispensary, I found the hand flexed, and the head of the middle metacarpal bone exposed in the palm. The patient complained of very great pain. Having thoroughly cleansed the parts with an antiseptic solution, counter-extension was made from the wrist and extension from the middle finger, pressure at the same time being made on the shaft of the metacarpal bone. The dislocation was easily reduced. The wound was not closed. An antiseptic dressing was used, and a splint applied from the elbow-joint to the ends of the fingers. The case did very well, without suppuration or impairment of the functions of the hand.

Bournemouth.

A VERY RARE PRESENTATION IN MIDWIFERY.

By J. R. BUCHANAN, L.F.P.S. GLAS.

THE very rare presentation in midwifery narrated by Mr. Borham in THE LANCET of Oct. 15th is certainly an unusual one, so far as my experience and reading have extended, but it is by no means unique. On Aug. 20th last I met with a case almost identical with that of Mr. Borham, but with a different result. The messenger who summoned me to assist the midwife, said that a loop of the cord had come down, but that the midwife had been able to replace it. On making an examination, I found a loop of the funis protruding from the vulva. It was quite cold and pulseless. A further investigation showed that the head and left hand were presenting, the hand lying closely pressed against the temple and cheek. I was able quickly and easily—the pelvis being roomy—to push the hand above the brim, and, applying the forceps, delivered in a few minutes, but the child had evidently been dead for some little time. The answer I got, on asking the nurse what she meant by saying that she had replaced the cord, was that she pushed it into the vagina under the impression that that made matters all right.

Glasgow.

DWELLINGS OF THE PEOPLE.—At a meeting of the members of the Mansion House Council on the Dwellings of the People on the 30th ult., it was reported that the inquiry ordered by the Home Secretary into the sanitary condition of Bethnal-green had been concluded, and that the Commissioners' report might shortly be expected. Meantime a very large proportion of the nuisances complained of had been remedied by the vestry. In Mile-end and in Limehouse district a similar condition of sanitary progress was reported.

UNIVERSITY COLLEGE HOSPITAL.

REMOVAL OF PART OF THE JAW, TONGUE, SIDE OF THE PHARYNX, AND SOFT PALATE FOR EPITHELIOMA.

(Under the care of Mr. ARTHUR E. BARKER.)

THIS case serves to illustrate some of the advantages of division of the cheek for the purpose of reaching disease far back in the tongue and pharynx, a measure which has yielded good results in the hands of many surgeons since first practised more than fifty years ago by Jaeger. The division of the cheek was here combined with removal of the lateral part of the jaw, which was in part involved in the growth. The rapid and uncomplicated convalescence after so severe an operation was remarkable, and most encouraging.

W. J. G——, aged fifty-five, was admitted on May 18th, 1885. He had already been operated on three times for epithelioma of the left tonsil and side of the pharynx, these operations consisting of thorough scraping with sharp spoons and the use of the actual cautery. In each case the wound had healed rapidly, but recurrence had taken place in a few months again. Still no trace of any glandular infiltration could be made out by the most careful examination. For some weeks before admission he had frequently requested further operation, as he was suffering from the most severe pain, quite beyond the control of cocaine, even when used in large quantity. It was explained to him that no operation short of removal of part of the cheek and jaw, as well as the tonsil and side of the pharynx, would now give him any relief, and would be a most serious procedure, and that probably the disease would even then recur. Nevertheless, in spite of dissuasion, he still pressed for the operation in order that he might have some cessation of pain, which was completely breaking him down, and his urgent request was acceded to.

At the date of admission the extent of the disease was as follows. There was difficulty of mastication and deglutition of hard substances. On the left tonsil and extending forwards over the anterior pillar of the fauces to the cheek, behind the molar teeth, there was an epitheliomatous ulcer with raised and thickened margins. The disease also spread above a little into the hard and soft palate, and below just on to the edge of the tongue. No affection of the glands was to be found anywhere. As there was no doubt as to the nature of the growth from examination of the tissues removed on former occasions, an extensive operation was clearly indicated.

Mr. Barker first made a slit from the left angle of the mouth to an inch and a half from the lobe of the ear. The facial artery was then secured below by a pin and figure of 8 of silk, and above by torsion. The last molar tooth having been extracted, the jaw was divided through its socket from above downwards and backwards, and all the angle, with part of the ascending ramus, was removed, the section of the ascending ramus being completed with bone forceps. With the bone were now removed by means of scissors, cutting well beyond the growth, half the soft palate and mucous membrane from the hard palate, the side of the pharynx and a considerable portion of the left side of the tongue, and a piece of the mucous membrane of the cheek and that lying over the ramus of the jaw. During this dissection three vessels were divided, which bled rather freely; these were probably the palatine and tonsillar branches. They were easily secured with Wells' forceps, and one was ligatured. The whole area of operation having been carefully dried, it was now dusted with iodoform. The divided cheek was then brought together with stout carbolised silk passed through everything but the mucous membrane, and a few finer stitches were placed between these. A dressing of salicylic wool was applied over all.

There was no shock, or very little, from the operation, and the next day the patient was sitting up in bed comparatively comfortable. The stitches were removed on May 24th, union by first intention having taken place except just at the posterior angle of the wound, which, however, soon closed. There were no complications, and the patient was discharged on June 8th, expressing himself as being more comfortable than he had been for twelve months. The temperature did not touch 100° except once, on the tenth day, when 100·6° was recorded in the evening; after this it was sub-normal until the patient left hospital. From this date the patient came backwards and forwards for examination for about a year. All this time there was no trace of recurrence or any pain, and he enjoyed the best of health. But at about the end of a year it was evident that a local return of the disease in the throat had taken place. This soon begun to ulcerate, and after several attacks of hæmorrhage he died at the end of fifteen months from the date of operation, after an attack of severe bleeding.

Remarks.—This formidable operation was only undertaken at the patient's earnest solicitation, and after explaining to him that it was not likely to be more than palliative. But the complete relief from suffering which it afforded, as well as the prolongation of life for more than a year, left no room for regret that it had been performed. It was remarkable that up to the end of the case no extension of the disease to the glands could be discovered. The result of this and other similar operations has left the impression on Mr. Barker's mind that more might be done in the way of excision of pharyngeal cancer than is commonly supposed.

MANCHESTER ROYAL INFIRMARY.

RUPTURE OF THE RECTUM; PERITONITIS; NECROPSY, WITH DISCOVERY OF A PIECE OF CLOTH IN THE ABDOMINAL CAVITY.

(Under the care of Mr. HEATH.)

THE following case was reported by J. Hilton Thompson, M.B. Vict., late house surgeon.

George C——, aged eighteen years, was admitted on May 20th, 1887. He stated that he had fallen about four feet, in a sitting posture, on to the end of the upright shaft of a smith's hammer, which he described as having entered his seat for a considerable but unknown distance, and requiring some amount of force in its removal, which was accomplished by a fellow-workman. He had very little pain at the time of the accident, and walked about a mile to the infirmary without much trouble.

On examination only some slight bruising was found around the anus, with a little blood-stained mucus. Per rectum nothing was detected. The abdominal walls were quite flaccid. Examination caused no pain. He complained, however, of a slight continuous aching pain just above the pubes. Soon after admission he passed both urine and fæces, the former normal, the latter soft and streaked with blood. Some hours later he passed another motion, with a considerable quantity of clotted blood; the suprapubic pain also became more intense, but the abdominal walls still remained flaccid. The face was very pale, the pulse rather weak, and the extremities cold; but the patient appeared to be in good spirits, answered questions readily, and did not feel unwell. He remained in this condition until midnight, when the abdominal pain became more severe. Symptoms of collapse gradually came on, and he died at 8 A.M.

At the necropsy on the same morning, the peritoneum was everywhere found intensely injected, and in parts presented a thin layer of lymph. There was a marked laceration in the recto-vesical pouch a little to the right of the middle line, which led into a triangular opening in the wall of the rectum, about three inches from the anus; this aperture was triangular, its base measuring one inch and a half, its sides an inch each. At the brim of the pelvis on the right side was a laceration of the peritoneum covering the psoas, with bruising of the subjacent muscle. The mesenteric glands were enlarged and inflamed. The abdominal cavity contained a small quantity of hard fæces; there was also found a piece of cloth corduroy, two inches long and one inch and a half in breadth, corresponding in texture to the patient's trousers and to an aperture in their seat.

The chief points of interest in this case appear to be: the slight amount of shock following so severe an injury to the

Digitized by Google

abdominal viscera; the few symptoms of peritonitis, which were found to have been very severe; the peculiarity of the lesion; and the presence of the piece of cloth in the abdominal cavity, it having evidently been carried onwards by the end of the hammer shaft.

WORCESTER GENERAL INFIRMARY.

CASE OF COMPOUND DEPRESSED FRACTURE OF SKULL; OPERATION; RECOVERY.

(Under the care of Mr. BUDD.)

WILLIAM K——, aged thirty-five, a coalheaver, was admitted on Oct. 3rd, 1887, with the following history. He had taken a cart-horse out of the shafts, and was passing behind it, when it kicked at a pony, and its hoof, passing clear over the pony's back, hit him on the head. He was unconscious for a few minutes.

On admission at 6 P.M. the patient was collapsed, his extremities being cold, pulse very feeble, and his respiration shallow; but he was quite conscious, and complained of no pain. In the centre of the right frontal region there was a linear wound running from above downwards two inches and a half long. There was practically no bleeding or bruising. Through this wound depressed and bare bone could be felt. At 9 P.M. his condition had improved a good deal, although his right upper eyelid had become swollen and of a dark colour.

Operation.—The head being shaved and strict Listerian precautions used, chloroform was administered, the patient requiring a very small quantity, and an incision was made downwards and outwards, running from a little above the centre of the wound to a point just above the lobe of the right ear. The wound was also prolonged at its lower end for an inch and a half, and the flaps turned back. This exposed the right temporal muscle, torn, and a large area of depressed bone. The muscle being turned back, two or three small loose pieces of bone were removed from the centre and from the anterior end of the wound, and this exposed a piece of dura mater about the size of a sixpence one inch above the eyebrow. With the bone forceps a slightly overhanging piece of bone was removed from the lower edge of the sound bone, and this allowed the depressed fragments to be easily elevated and removed. This showed about half an ounce of blood clot on the surface of the dura mater, which was removed, and that membrane found to be uninjured. A piece of loose bone the size of a shilling in the upper angle of the wound was elevated, but as it was still adherent to the periosteum it was allowed to remain. Slight bleeding from branches of the anterior division of the middle meningeal artery was easily stopped by passing a silk ligature under it, and then tying it. A drainage tube was inserted, and the wound closed with silver sutures. It was then dressed with iodoform and corrosive sublimate wool.

On Oct. 4th the patient presented no symptoms whatever; the wound was dressed, and half the tube removed. Temperature normal; pulse 84; respiration 20. He was kept on liquid food and in a darkened corner of a general ward. On the 5th, at 8 P.M., the temperature went up to 101° F., and the wound was again dressed; but there being no discharge, and the wound looking perfectly healthy, the tube was removed, and the next day the temperature was normal, and remained so, the patient being allowed to eat some fish. On the 9th the sutures were removed, and on the 10th the patient sat up for half a day, being out of bed all day on the 16th, since which date he had been getting about all day, in perfect health.

Oct. 31st.—A depression now occupies the situation of the original wound, and pulsation is observed in it over an area measuring an inch and three-quarters from side to side and two inches from above downwards. Pressure in this situation causes no pain whatever. The vertical limb of the scar measures three and the horizontal limb four inches. Twenty-three pieces of bone were removed, the largest being two inches long and one inch broad, and two others being an inch long and three-quarters of an inch broad, and half an inch long and half an inch wide respectively, the remaining pieces being mere fragments. Careful measurements show that the whole of the area from which bone was removed would be in front of the ascending limb of the fissure of Sylvius, and therefore corresponding to the position of the lower and middle frontal convolutions of the brain.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Removal of Tumour from Female Bladder by Supra-pubic Incision.—Hysterical Hyperpyrexia.—Congenital Absence of Upper Lateral Incisor as a forerunner of Hare-lip and Cleft Palate.

AN ordinary meeting of this Society was held on Nov. 25th, Dr. W. H. Broadbent, F.R.C.P., President, in the chair.

Dr. GIBBONS and Mr. PARKER contributed a case of Tumour (myoma) of the Female Bladder removed by the galvano-cautery through a dilated urethra combined with supra-pubic incision; illustrating, also, the value of the electric light for purposes of exploration of the bladder. The patient was a girl, aged eighteen, of good general health, and the daughter of healthy parents. The earliest symptoms noticed were inability to retain the urine, and pain on making effort to do so. She was treated "for stone in the bladder, but without any relief." When admitted into the Grosvenor Hospital for Women and Children, she was found to have lost all control over the urine, which dribbled away from her; she experienced a dull aching pain in the perineum. There was no blood in the urine at the time. On bimanual examination, a tumour was detected in the bladder; rapid dilatation of the urethra was accomplished with a view to a more accurate examination of this tumour. A week subsequently, the patient being under an anæsthetic, the tumour was removed by means of a galvano-cautery écraseur; the loop of platinum wire was introduced through the urethra, and fitted over the tumour with the aid of the fingers passed into the bladder through a supra-pubic incision which had been previously made for this purpose. When the platinum loop had been fixed round the base of the tumour, it was tightened up and the current turned on. In five minutes the division of the tumour was complete; there was no hæmorrhage during, or subsequently to, the operation. After removal the base of the growth and the interior of the bladder were carefully examined by the eye, a small incandescent electric lamp being introduced for the purpose; the advantages of this method were at once very apparent, for every part of the bladder could in turn be seen. The wound into the bladder was carefully sutured. There were no subsequent bad symptoms. The girl quickly and completely recovered, and has remained well since. In some remarks which followed the paper the authors advocated a supra-pubic incision in similar cases, and recommended the use of the electric light. They also drew attention to the value of carefully suturing the bladder after supra-pubic cystotomy, as materially aiding towards a rapidly successful result.—Mr. CROFT said that the case was a very rare one in so young a female. He concurred in the treatment of the tumour by opening the bladder. He related a case of vesical stone in a boy, employing the suture; on the third day after lithotomy scarlet fever appeared, but, notwithstanding, the sutures held and the bladder healed naturally. Tumours could be removed from the bladder without the aid of sight. Severe cystitis with fetid urine would contra-indicate closure of the bladder.—Dr. BRAXTON HICKS had removed two tumours from the posterior wall of the female bladder by dilatation of the urethra and snaring the tumours, which had each a diameter of one inch and a half, by means of a silver wire. Both cases were malignant. The galvano-cautery would prevent bleeding.—Mr. BUCKSTONE BROWN thought it would be impossible in most cases to make use of light; everything has to be done by the aid of mere touch, which was quite sufficient for all cases. In order to use the cautery it was unnecessary to see exactly what is being done. Straight forceps will, by "quiet" torsion, bring away even the toughest tumour. Phosphatic matter was apt to be deposited on the base of a tumour which had been removed.—Mr. J. H. MORGAN considered that the electric light was not generally useful in the removal of tumours from the bladder in adults. In some cases in children the light would be useful. The drawing of the tumour had the aspect of a papilloma. He did not think the wound closed speedily, and he should not have used a drainage tube in Mr. Parker's case. He would be inclined not to employ the suture.—Mr. BENNETT asked why the supra-pubic incision was employed, for such an operation could hardly be often necessary; what were the exact reasons for this mode of

Digitized by Google

operation? In the female bladder the necessity for this incision must be extremely rare. Mr. R. W. PARKER, in reply, said he would only suture a healthy bladder. In Mr. Brown's cases the electric light would be extremely useful after the operation to examine the parts and for employing the actual cautery. The supra-pubic operation was not a serious one in his experience. Mr. Shattock agreed that the tumour was a myoma.—Mr. CROFT said that the notion advanced by Dr. Braxton Hicks that the malignant disease would tend to spread to the edges of the fresh wound was imaginary.

Dr. A. H. CLEMOW read the notes of a case of Hysterical Hyperpyrexia. The patient, a laundrymaid, aged twenty-three, was admitted into the Edinburgh Royal Infirmary, Oct. 22nd, 1883, under the care of Dr. Brackenridge. She was complaining of dizziness and pain in the left side, and presented a purpuric rash upon the lower extremities. The first high temperature (107·8°) was recorded on Nov. 29th, the day following a fright she had received from seeing a man who had lost his eye. At midnight the same night three records were successively taken, the first giving 111°, the second 108°, and the third 98°. At noon on Nov. 30th, a first record gave 110°, a second 99·6°. Taken under both axillæ at the same time, at 4 P.M., the temperature was, right side 108°, left 99·4°; at midnight, right side 98°, left 108°. Dec. 1st, 6 A.M., right 107·2°, left 98·4°; 9 A.M., right 100°, left 98°; 6 P.M., right 108·4°, left 98·8°; 9 P.M., right 99·2° left 108·6°; midnight, right 98·2°, left 105°. Dec. 2nd, 3 A.M., right 97·8°, left 108·4°; 6 A.M., right 107°, left 98·4°; 9 A.M., right 109·2°, left 99·2°; 12 noon, right 99°, left 109·2°; 3 P.M., right 109°, left 99°; 6 P.M., right 110·2°, left 98°; midnight, right 105°, left 98°. Dec. 3rd, 3 A.M., right 109°, left 98°; 9 A.M., right 98·8°, left 109·2°. Dec. 4th, 9 A.M., right 99·9°, left 98·4°; 12 noon, right 98°, left 99·2°; 6 P.M., right 108·8°, left 99·8°. On Nov. 30th, several short, but severe, spasms simulating tetanus occurred. On Dec. 1st, apart from persistent headache and nausea, there was a peculiar and constant elevation and depression of the eyelids. There was also a slowed reaction to light of the right pupil, and left internal strabismus. There was throbbing pain at the vertex, increased by pressure, which also was capable of inducing the pseudo-tetanic spasms above described. On the 3rd the spasms were of frequent occurrence, and during their continuance the heart's sounds became muffled, its beats doubled in rapidity, and the pulse at the wrist imperceptible. At night the head was shaved, a blister applied over the vertex, and the patient removed to a private room. A quarter of a grain of eserine was administered hypodermically, which, after an interval of wild delirium, appeared to exercise a soothing effect. On December 4th she was delirious, talking much about her eyes, and spasms were frequent and violent. A marked difference, appreciable to the touch, was noticed in the temperature of the two sides. From December 4th to the 13th she was unconscious, appearing to sleep at times, and occasionally very restless, delirious, and violent. Plantar and patella reflex were absent; there was cutaneous anæsthesia at first, and incontinence of urine and fæces during the greater part of the time. On the 5th the tetanic spasms could be increased in frequency and severity by pressure upon the left side of the abdomen. Consciousness returned on the 13th, and during the next few days control of the bladder and bowel was regained. On the 18th there was a slight relapse, and erythema appeared on the arms, which had vanished next day. On January 3rd the chimney of her room caught fire, the fright causing a return of tetanic symptoms, which had passed off by evening. She now steadily improved till January 12th, when her temperature was 110°; a second record taken immediately afterwards gave 98·4°. She remained under observation till April 1st, improving all the time. She would occasionally exhibit outbursts of temper, and would sometimes remain sulky for two or three days. On one occasion there was a threatening of a return of the symptoms, which soon passed off. She slowly regained her strength, and, although highly sensitive and emotional, was, on leaving, otherwise quite well.—Dr. ORMEROD mentioned a case in a middle-aged woman in which the temperature used to rise in places to 116°; this patient, amongst other nervous symptoms, had delirium.—Mr. BERNARD O'CONNOR asked whether antifebrin was used.—Dr. HALE WHITE had collected all the recorded cases, seventeen in number; he contended that such cases could be explained on physiological knowledge concerning thermic centres in the brain. A German had recently written on the various modes in which deception may be practised. No cases had been observed in males, who could deceive as well as females.—Dr. DAWTREY DREWITT contended that such sudden falls in temperature as occurred in Dr. Clemow's case were physical impossibilities.—Dr. STEPHEN MACKENZIE said the temperature might be taken on the two sides simultaneously, and also by using two thermometers on the same side. This detected the fraud in his own case of hyperpyrexia (120° F.).—Dr. BROADBENT said his attitude was one of suspense of judgment. If the cases were real, and not due to deception, then the thermic centres must literally "blow hot and cold" in the same parts.—Dr. CLEMOW, in reply, said precautions had been taken to prevent deception, but he had himself taken the temperature a few times only; he had not used two thermometers in one axilla. The temperatures were always registered in the axilla.

Mr. R. CLEMENT LUCAS read a paper on the Congenital Absence of an Upper Lateral Incisor Tooth as a Forerunner of Hare-lip and Cleft Palate. He said the tendency of deformities to repeat themselves in succeeding generations, and even to exaggerate their defects, rendered an early recognition of their presence of some professional importance. He alluded to a family history he had published in the Guy's Hospital Reports for 1880, where he had traced eighty descendants of a woman who had supernumerary fingers and toes, and found that 30 per cent. were so affected. A case showing the hereditary tendency in hare-lip and cleft palate had come under his care in August of this year. A woman who had been successfully operated upon married, and had six children. The second child and the sixth presented the same deformity as the mother, the others escaping. The object of this paper was not, however, to discuss the repetition of pronounced deformities, but to show the danger of a deformity partially developed and likely to pass unobserved. He wished to point out (what he did not think had hitherto been described) that the congenital absence of an upper lateral incisor tooth may foretell the probability of cleft palate and hare-lip in a succeeding generation. He had been most careful to exclude any possibility of error through decay or extraction of the tooth in question. He illustrated his paper with three cases. The first, a man with congenital absence of the lateral incisor on the left side, had a daughter presenting precisely the same defect. The second, a woman aged twenty-five, who had a congenital absence of the right upper lateral incisor, brought her fifth child with right hare-lip. The third, a woman aged twenty-three, having congenital absence of the left upper lateral incisor, brought her first child suffering from hare-lip and cleft palate on the left side. His observations were few, and had extended over ten years, but the association of these defects was too remarkable to go unrelated. Had he been able to examine both parents, which was seldom possible in hospital practice, it is probable he might have collected more cases. Now that attention had been drawn to the observation, it was likely that more cases would be collected. The author held the following deductions to be irrefragable: That the congenital absence of an upper lateral incisor tooth resulting from an arrest of development is to be regarded as a malformation closely related to hare-lip and cleft palate, and capable of transmitting each or both of these deformities to a succeeding generation.—A Dental Member said that absence of the lateral incisor was of very common occurrence.—To this Mr. CLEMENT LUCAS replied that the frequency of the loss was not an explanation of the absence of the tooth.

MEDICAL SOCIETY OF LONDON.

Radical Cure of Hernia.—Hysterical Tremor and Contracture.—Persistent Branchial Cleft.—New Form of Truss.—Myxœdema.—Dizziness.—Plastic Operation for Ectropion.

THE meeting of this Society on Nov. 28th was a "clinical evening," and many cases of interest were shown. The chair was taken by the President, Dr. J. Hughlings Jackson, F.R.S.

Mr. BOWREMAN JESSETT read notes of two cases of Radical Cure of Hernia. The first case was a man aged fifty-seven, a beadle, who had a double scrotal rupture for twenty years. An incision two inches in length was made over the external abdominal ring, the sac was exposed and separated from the surrounding structures as high as the internal ring; it was then opened and some omental adhesions detached. The neck of the sac was twisted and tied with a ligature of silkworm gut, which was first made to transfix it, in order to

Digitized by Google

prevent the possibility of slipping. The body of the sac was cut off and the ligatured stump fixed in the external ring, the pillars of which were sutured together. This served the double purpose of effectually plugging the ring and of preventing the possibility of the stump retracting from the ligature around it. The same procedure was carried out on the opposite side, and the patient made a speedy recovery, being enabled to return to his work, wearing a light truss as a support. The second case was one of large femoral hernia in a woman of six months' standing. The sac was exposed, a large mass of omentum removed, and its stump returned to the abdomen. The body of the sac was then detached, the neck twisted, transfixed, ligatured, and fastened in the crural opening. The method was advocated as being less painful and dangerous than that adopted by Mr. Wood, and preferable to obliterating the sac by the injection of irritant fluids. The importance of detaching the sac as high as possible, of opening it before applying a ligature, and of fastening the stump in the wound, was insisted on.—Mr. BERNARD PITTS said that in two of the cases he had operated on there was a tendency to relapse. After operation patients were enabled to wear a truss with greater comfort.—Mr. WALSHAM had operated on many cases, but had only had one relapse, a case of large umbilical rupture. He advocated entire closure of the pillars by suture as being preferable to blocking the ring with the pedicle.

Dr. ORMEROD showed a woman, aged twenty-nine, who was suffering from Hysterical Tremor of the Hands, with tonic contracture of the flexors of the fingers and toes. The illness commenced fifteen months previously, the patient having then rheumatic fever. The tremor, which developed after a fit and had lasted six months, consisted chiefly in an up-and-down movement of the wrists and forearms; it was more marked during attempts to use the hands, and was very slight during sleep. The contracture existed two months, developing first in the left hand after a fit, and in ten days spread to the right hand and both feet. The thumbs were unaffected; the toes were clenched, like the fingers, rendering walking difficult. She had been treated by tonics, faradisation, and static electricity.

Mr. W. PYE exhibited a case of Symmetrical Branchial Fistulæ in a child nine months old. One of the openings he had proved by probing to lead into the lower part of the pharynx; the other, he suspected, did so also. The only other abnormality noticed was a trifling arrest of development of the mid-phalanx of each little finger.—Mr. PICK referred to a case in which a patient, his mother, aunt, and two sisters all had branchial fistulæ. The application of the actual cautery would not bring about occlusion of them.

Mr. PYE likewise demonstrated the application of a New Form of Truss, which took its bearing on the pubic bone. Anteriorly and laterally it was made of a band of gun-metal, which could be easily moulded by the patient; behind it was completed by a broad elastic webbing.

Dr. SAVILL brought forward the case of a man, aged thirty, the subject of Myxœdema. He presented the expressionless aspect, scanty hair, slow and feeble movements, great susceptibility to cold, and subnormal temperature characteristic of the disease; in addition he had complete loss of memory. The quantity of urine per diem, specific gravity, and amount of urea were all below normal, the latter markedly so; there was no albumen. Soon after coming under observation he had profuse hæmorrhage, apparently from the prostate gland. There was no paralysis, and common sensation, though much delayed, was otherwise good. The power of comprehension and reasoning were fair, but volition was feeble. He was not emotional or melancholic, and had no definite delusions. The pulse tracing showed a low tension, and there was neither enlargement nor appreciable atrophy of the thyroid gland. The disease was sufficiently rare in the male to make this example of interest; Dr. Savill was aware of only nineteen recorded cases, or 13·5 per cent. of all those published. Slowness of all the mental processes was a usual condition of the disease, and some cases had shown signs of insanity in the latter stages, but he was not aware that loss of memory had been so marked and isolated a feature as in the case he described. Hæmorrhage might now be regarded as one of the symptoms of the disease; the slight irritation of catheterism seemed to have determined its seat in the present instance.

Dr. C. E. BERVON showed a woman, aged fifty-three, who was suffering either from Myxœdema or from Stagnant Œdema after Erysipelas. She had been under the care of Dr. Gowers for the effects of a blow on the right side of the head from being thrown against the wheel of a bathing machine, inflicted seven years ago. She had no weakness or paralysis at the time, but complained of pain in the right side of her head and body. Six months afterwards she had œdema of the eyes, and four years later still an attack of erysipelas. The puffiness of the eyelids had increased of late and she had become more feeble. The face was pale, the cheeks high coloured, the expression mournful, the skin slightly dry, the speech slow and monotonous, and her general condition one of mental hebetude. She felt the cold, her hair had come out, and she had lost several teeth.—Dr. FELIX SEMON and Dr. BRISTOWE considered the second case to be one of "stable œdema" after erysipelas.

Dr. HERRINGHAM exhibited a man, aged twenty-nine, who for two years had had Dizziness on throwing his head back. As long as his head was level he felt nothing, but he had on two occasions fallen backwards when inadvertently looking upwards, and had to give up being shaved owing to a feeling, when his head was laid back, that the ceiling was coming upon him. He had occasional vertical pain in the head for about three years, and for two months continual nausea and vomiting; there was no optic neuritis or paralysis, nor had there ever been any convulsion; the knee jerks were rather brisker than usual, and there was a tendency to ankle clonus. A cerebellar tumour was suggested to explain the symptoms.—Dr. HUGHLINGS JACKSON referred to a case in which pressure on a diseased ear caused sickness, with movements of the eyes towards the same side.—Mr. JAMES BLACK advocated the administration of quinine combined with hydrobromic acid.

Mr. SPENCER WATSON showed a case of Ectropion which had been treated by a plastic operation. The ectropion had followed the contraction of a lupoid scar on the cheek. A flap was dissected from the temporo-malar region, and placed in the gap left by dissecting up the lower lid, and the result was excellent.

OBSTETRICAL SOCIETY OF LONDON.

A SPECIAL MEETING of this Society was held on Wednesday, Nov. 23rd (Dr. John Williams, President, in the chair), for the discussion of the treatment of extra-uterine gestation during the latter months of pregnancy.

A paper was read by Dr. Herman on Delivery by the Vagina in Extra-uterine Gestation. The author said that no general rules could be applied alike to all cases of extra-uterine gestation and at all periods of their history. Different cases required different treatment, and individual cases required different treatment at different periods in their history. The object of the paper was to consider in what cases and at what time an extra-uterine gestation cyst might with advantage be emptied through the vagina. The author first related a case under his own care. The patient was forty years of age. The extra-uterine pregnancy was preceded by a long period of sterility. Symptoms like those of rupture of the sac occurred at about two months' pregnancy. Fœtal movements ceased at eight months' pregnancy. At nine months spurious labour pains occurred, and lasted nearly a month, and these labour pains were accompanied by spontaneous dilatation of the cervix. Then the pains went off, the breasts diminished in size, and the cervix contracted. To attain certainty as to the diagnosis, the cervix was subsequently dilated, and this dilatation was followed by febrile disturbance. The cyst was then opened per vaginam, the child removed, and the cyst frequently washed out with carbolic solution. The placenta came away on the sixteenth day. Two months and a half afterwards the cyst had completely closed. The author had collected thirty-three cases in which an extra-uterine gestation cyst had been emptied by the vagina, and from an examination of them he drew the following conclusions: 1. The operation of opening an extra-uterine gestation sac by the vagina early in pregnancy, before rupture has taken place, by the cautery knife or otherwise, is a dangerous and unscientific proceeding. Abdominal section ought always to be preferred to this. 2. Soon after rupture has taken place, when interference is called for to arrest hæmorrhage, abdominal section is more likely to succeed than vaginal. 3. When rupture has taken place, and the effusion of blood is followed by pyrexia, the indications for incision of the vagina are the same as those in hæmatocele from any other cause. 4. At, or soon after, full

Digitized by Google

term, before suppuration has taken place, there may be conditions which indicate delivery by the vagina as preferable to abdominal section. These are, 5, when the fœtus is presenting with the head, breech, or feet, so that it can be extracted without altering its position, and, 6, when it is quite certain, from the thinness of the structures separating the presenting part from the vaginal canal, that the placenta is not implanted on this part of the sac, and it is not certain that the placenta is not implanted on the anterior abdominal wall. 7. If the child cannot be delivered by the vagina without being turned, abdominal section should be performed. 8. No attempt should be made to remove the placenta. 9. The after-treatment should consist in frequent washing out of the sac. 10. After suppuration has taken place, the spontaneous opening of the sac into the vagina is one of its more favourable terminations.

A paper was then read by Dr. CHAMPNEYS on Primary Laparotomy (that is, Abdominal Section in the Latter Half of Pregnancy, the Child being alive) in cases of Extra-uterine Gestation. The operation was performed in the seventh month of pregnancy for persistent and increasing pain and orthopnœa. The placenta was left; drainage was attempted, but the wound could not be kept open. The decidua was discharged on the twenty-fourth day. All went well till the thirty-second day, when symptoms of the separation of the placenta began, and the patient died, with symptoms of septic intoxication, eleven weeks and a half after operation. Post mortem the placenta was found detached; no hæmorrhage of importance had taken place; it lay in a nest of intestines and adjacent organs.

Dr. JOHN WILLIAMS then related a case of Extra-uterine Pregnancy, in which abdominal section was performed during the life of the fœtus at the thirty-fifth week of gestation. The patient was thirty years of age, and had had one child nine years before. She was admitted into University College Hospital when about four months pregnant. For six months she had suffered from almost continuous hæmorrhage, but this ceased about the time that conception took place. She then suffered from attacks of pain in the right iliac fossa, and when pregnancy had advanced into the fourth month she had severe pain in that place, hæmorrhage from the uterus, and general peritonitis. A decidual membrane was also expelled. When admitted into hospital in February, 1885, she was suffering from peritonitis. She remained in hospital till August. The growth of the cyst and of the placenta was observed and described. In the thirty-fifth week the abdomen was opened and a living child removed; the placenta was left. The subsequent progress of the case towards recovery was detailed.

Mr. DORAN showed specimens which illustrated the changes which the placenta underwent after term, and he related a case under his care. The patient menstruated for the last time in April, 1885. In January, 1886, labour pains and metrorrhagia occurred. Diagnosis was uncertain for several reasons. In April, 1886, an exploratory operation was performed. A very malignant-looking tumour was exposed, dark-red in colour, and on plunging in a trocar no fluid escaped. Believing that the tumour was malignant, Mr. Doran proceeded at once to remove it, lest fatal hæmorrhage should occur before its vessels could be secured. In raising the tumour it burst posteriorly, and a large fœtus escaped. A clamp was passed round the base of the tumour, and it was cut away. The patient died, probably owing to injury to the intestine. The dark-red mass in the front proved to be placenta hypertrophied and much altered.

Mr. KNOWSELY THORNTON was happy to be able to agree in the main with the propositions formulated by Dr. Herman; with the first and second he entirely agreed. He thought that the third was hardly precise enough, as there might be great differences of opinion as to the treatment of hæmatocele under such conditions; he should be strongly in favour of abdominal section. He did not know the grounds Dr. Herman had for believing in the absorption of the fœtus, but he knew from clinical observation that the blood effused in these cases was not readily absorbed, absorption being very different to that with which we are familiar in large fresh outpourings of blood such as hæmatoceles. As to the question of operation through the vaginal wall, he doubted whether in most cases the diagnosis could be as easily made as Dr. Herman would lead one to suppose, and he did not think the risk of injuring a coil of intestine was a small one, though this was not mentioned by Dr. Herman. He thought that, with the present means of controlling hæmorrhage, the possibility of the placenta being situated on the abdominal wall need not be such an alarming complication of abdominal section as to influence the choice of operation. Passing to Dr. Champneys' case, he would say that the whole question of primary laparotomy hinged on perfect diagnosis, and, knowing how often there was something wrong with the child in these cases, he would disregard it altogether and simply consider the mother, and urge that operation should follow at once on certain diagnosis. The whole difficulty was in making such certain diagnosis. He could not understand Dr. Champneys' treatment of the placenta. If it was left, there ought to be certainty of asepsis (very difficult to attain in these cases), or an opening should be kept till the placenta was discharged. Dr. Champneys knew it was attached to intestines, the very situation of all others in which it was likely to become septic or a source of danger. His own cases on the table were mostly excluded, owing to the restriction of the debate to a certain class of cases.

Dr. W. S. GRIFFITH showed a series of specimens from St. Bartholomew's Hospital museum, and also a six months' fœtus, removed by Dr. Godson by vaginal incision about ten days after the death of the fœtus. The head presented at the posterior vaginal fornix, and was delivered by craniotomy. The placenta was detruded on the sixth day and removed. There was no hæmorrhage at or after the operation. The parts were kept aseptic by frequent irrigation and iodoform, and the patient left the hospital within three weeks after the operation.

The PRESIDENT said that hitherto the difficulties in the treatment by laparotomy of extra-uterine pregnancy while the fœtus was alive had been the risk of septicæmia and of hæmorrhage. Antiseptics had greatly reduced the former, and the danger of hæmorrhage, in so far as was known, remained the same. Hæmorrhage was of two kinds, one occurring during the operation from injury to the placenta, and the other after the operation from separation of the placenta. Further observations might enable us to diagnose the presence or absence of the placenta on the anterior abdominal wall, and to avoid it in performing the operation. The danger from the second form occurred in the same degree after the death of the fœtus, and no safe way of dealing with it was known. The power of diagnosing the placental site would contribute greatly to the more successful treatment of these cases.

Mr. LAWSON TAIT regretted the restriction of the debate to a certain class of cases only. He felt that little was left for discussion. There were three points about which something might be said. The first was as to the fear of meddling with the placenta, and he entirely agreed with what had fallen from Mr. Knowsley Thornton, and differed from the remark made by the President, that with our modern appliances we had no need to fear hæmorrhage. Mr. Tait had recently operated on a case in which the placenta had to a large extent left the ruptured Fallopian tube and obtained attachment to the posterior wall of the uterus and some coils of intestine. When disturbed, pretty free arterial hæmorrhage took place. The stripping of the placenta was proceeded with as far as necessary, the bleeding points were touched with solid perchloride of iron, and no more hæmorrhage was heard of, and the patient made a good recovery. The next point of interest was the growth of the placenta after the death of the fœtus. Mr. Tait used to disbelieve that this growth occurred, but there could be now no question that it did so in a large number of these cases. This being so, what was the use of destroying the fœtus by electricity, as the placenta continued to grow, and it was not the fœtus that was a source of danger, but the placenta? The third point was the difficulty of diagnosis, and his experience was precisely that of Mr. Thornton, but he never allowed any uncertainty to stand in the way of trying to save his patient, and he in doubtful cases opened the abdomen.

Dr. GALABIN and Dr. GRAILY HEWITT made some remarks, and then Dr. HERMAN, in reply, said that it was impossible to adduce evidence that absorption of the fœtus and effused blood took place, because such cases recovered. He thought that many cases of pelvic hæmatocele that ended in recovery were probably due to unsuspected extra-uterine gestation. Leopold had made some experiments on animals that supported this opinion. He opened the uterus in animals a little way advanced in pregnancy and turned the embryos into the peritoneal cavity. He found that they were absorbed. Dr. Herman was inclined to agree with Mr. Thornton, that if a

Digitized by Google

hæmatocele required opening, it was better to open it by the abdomen than by the vagina, unless the latter course was specially indicated. He did not think there was difficulty in recognising the fœtal head when it occupied Douglas's pouch and the placenta did not intervene. The sutures could often be felt, and then there need be no fear of wounding the intestine. The condition of the placenta was of great importance. There were two kinds of placentæ met with in extra-uterine gestation. One kind was thin and spread out, having extensive attachments difficult of complete removal, and much more difficult at term than at the fourth month, as in Mr. Tait's case. There were others in which the placenta formed a thick solid mass, and in this kind the vascular attachments to the maternal structures were much less extensive, and the placenta could be removed without great difficulty. He had exhibited such a one to the Society which he had successfully removed quite easily. The placenta shown of Dr. Champneys' case was similar, and he gathered that it was so loose that it might have been removed. Mr. Thornton had exhibited another, Mr. Doran's was another instance, and there was another in the museum of the Royal College of Surgeons. Judging from the cases at present known to him, he thought this placental growth took place after the death of the fœtus. It would help greatly in treatment if we could diagnose the condition of the placenta before operation.

Dr. CHAMPNEYS, in reply to Mr. Thornton, said that both the paper and abstract plainly stated that, with the exception of four transient rises of temperature during the first six days, the temperature was normal, and the patient remained well for thirty-three days. He thought this was evidence that the operation was aseptic. Mr. Thornton had said that the author should not have allowed the wound to close. As a fact, he had done his best to prevent it. He left the cord hanging out, and put two large drainage tubes in. When the cord became adherent to surrounding parts, and the drainage tubes absolutely blocked by organised lymph, he felt powerless to prevent it. In Dr. Braithwaite's case the placenta never came away, and in other cases the placenta has not only lived but grown after the death of the fœtus, and he did not know why the placenta in his case should not do the same if kept aseptic, which he had no doubt it was. In another case he would act as he had done in this, except that he should operate a second time if need be, and try to remove the placenta. He had pointed out that in several respects his case was unique, and thus he was deprived of the guidance of other cases.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this Society was held on Nov. 22nd at University College. The following papers were read and discussed.

Dr. MOTT showed Microscopical Sections and Microphotos to illustrate the shape and size of the cells of Clarke's column in the dog, monkey, and man. He pointed out that by making vertical as well as transverse sections he had been enabled to determine the size of these cells and their connexions. The cells were either distinctly bipolar or vesicular, with large and distinct axis cylinders and processes. The long axis of the cell was placed vertically, and the cells were connected below with fibres of the postero-external column, and above by fibres, which in vertical sections could be traced outwards and upwards to the direct cerebellar tract. This point was further supported by numerous pathological specimens which showed degeneration of either of the upper or lower segments of nerve fibres, according to the position of compression, in relation to Clarke's column. Dr. Alexander Hill commented upon the measurements of the cells given by Dr. Mott, and said the anterior vesicular columns were the first to develop, whilst Clarke's column came later.—Professor STEWART asked some questions, and Dr. MOTT replied.

Professor WINDLE then read a paper upon the Arteries forming the Circle of Willis. Two hundred cases were examined, and abnormalities found in eighty-one. The anterior communicating artery was often double; once three were found. Occasionally a third anterior cerebral artery (arteria cerebralis anterior media) was present, and came from the anterior communicating. Twice one of the anterior cerebral arteries was absent in the right side. The commonest abnormality of the posterior cerebral arteries was their origin from the basilar. On the whole, the blood-supply of the left side of the brain was less complete than the right; also the absence or diminution of the left posterior communicating artery might help to explain the lodging of embolism in the left middle cerebral arteries.—Mr. BLACK mentioned a case in which the internal carotid artery made a complete bend before entering the skull.—Professor MACALISTER mentioned cases of divided basilar arteries, and said that the evidence went to show that all median arteries were formed by fusion.

Professor Sir WM. TURNER, F.R.S., then communicated a paper by Mr. R. Howden upon the Variations in the Hippocampus Major and Eminentia Collateralis in the Human Brain. The paper was illustrated with numerous drawings and casts of brains, and went to show that the usual position of the eminentia collateralis was sometimes occupied by a depression, or that the eminence might extend down the middle horn of the ventricle. When the hippocampus major was small its fissure had little depth, but, as a rule, the direction of the various fissures, and not their depth, determined the prominence of the elevations caused by them in the interior of the brain.

Professor Sir WM. TURNER also communicated a paper by Mr. David Hepburn upon a Needle in the Spinal Canal transfixing the Roots of the Spinal Nerves. The paper was accompanied by a specimen, and it was probable that the needle, which was really an inch and a half long, had been in the spinal canal some time.

The following specimens were then shown and demonstrated:—1. Methods of preparation, preservation, and mounting: (*a*) mounting of certain dried preparations; (*b*) moist method for dissections and museum preparations; (*c*) method of preparing the brain (Professor Struthers). 2. Specimens of (*a*) Rider's bone; (*b*) series of specimens of permanently separated acromion process, simulating fracture; (*c*) series of preparations of the variety in which the right subclavian artery arises last from the arch of the aorta (Professor Struthers). 3. The lungs in *situs inversus* (Professor Thane). 4 Separation of acromial and coracoid epiphyses (Professor Curnow).

It was announced that the next meeting would be held in February, at King's College.

ÆSCULAPIAN SOCIETY.

A MEETING of this Society was held on Friday, Oct. 21st, Dr. J. F. Woodroffe, President, in the chair.

Dr. ALEXANDER MORISON read a paper on the Mechanism of Cyanosis, including a synopis of seventy-five collected cases of cardiac malformation. This paper was the sequel of one read before the Society on Feb. 18th on the case of a child, aged seven years, in whom fatal cyanosis was found on post-mortem examination to have been associated with the following physical condition. The ductus arteriosus was closed, the pulmonary artery narrowed to an eighth of an inch, the septum ventriculorum imperfect at its base, the aorta arising at this point from both ventricles. Cyanosis was present from birth, and had become most marked during the last two years. It was attended with severe attacks of dyspnœa. Dr. Morison regarded the state of the ductus arteriosus in relation to the pulmonary artery as most important. The former channel was open in forty-six of his collected cases, closed in eighteen, and doubtful in the rest. He found that in the first group cyanosis appeared earlier, and the duration of life was shorter than in the second. As regards the mechanism of cyanosis, he considered the chief though not the only agency at work was a diminution of the aspiration exercised by the lungs.

Dr. JOSEPH W. HUNT read notes of a case of Cerebral Syphilis. J. C —, male, aged thirty-six, had partial right hemiplegia and pain along the left side of the head. Later the left third nerve was paralysed. There was atrophy of the left optic disc (the patient had only one eye). Subsequently, aphasia, with right facial paralysis, appeared. The intellect was impaired. All symptoms, except the optic atrophy and in some degree the left ocular paralysis, disappeared under large doses of iodide of potassium. The diagnosis was: basal gumma pressing on the left third nerve and crus cerebri, afterwards involving the region of the pons Varolii. The exact significance of the aphasia, mental weakness and optic atrophy, however, remained somewhat doubtful.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

A MEETING of the above Society was held on Oct. 13th, Dr. G. H. Hume, President, in the chair.

The Honorary Secretary, Dr. OLIVER, read the annual report of the past year, which was highly satisfactory, both as regards the finances of, and the number of members in, the Society—the latter being 163.

Dr. MURPHY exhibited a patient upon whom he had performed Gastrostomy by Tillaux's method on Sept. 10th for Cancer of the Œsophagus, and a woman upon whom he had performed Glossectomy for Cancer of the Tongue. Dr. Murphy, in his remarks, drew attention to the rarity of cancer of the tongue in women, a point touched upon by subsequent speakers, as also the period when operation should be performed, the feeling of the President and Dr. Murphy being that so long as pulpy food could be swallowed it was undesirable to operate.

Dr. DRUMMOND exhibited three patients suffering from Locomotor Ataxia, all men. The first had been ill for two years, had suffered much from gastric crises, was now myotic, *but still retained his knee jerk*—a point of great importance, considering the length of time he had been ill. The second patient had paralysis of the third nerve of the eye on one side, with paralysis of the sixth and partial paralysis of the third on the other side; whilst in the third patient, a young man of twenty-three, and who had been ill for four years, the illness had begun with paralysis of the third nerve.—Dr. WATSON of South Stockton raised the question of the relationship of locomotor ataxia to injury, giving particulars of a case which had come under his care.—Dr. DRUMMOND thought that in many of these cases the ataxia preceded the injury.

Mr. PAGE exhibited a Calculus removed from the bladder of a child, aged four years, by the suprapubic method. The incision was made one inch above the pubes; the bladder was not sutured, and within fourteen days the boy left the infirmary quite well. Mr. Page's remarks gave rise to an interesting discussion as to the comparative methods of lithotomy—the lateral and suprapubic. Drs. Hume, Anderson, Murphy, and Flynn took part in the debate.

Dr. MURPHY exhibited a Testicle and a portion of Omentum removed by a man in operating upon himself for strangulated hernia. In spite of the severity of the self-inflicted wounds (the patient was at the time a lunatic), the man made a good recovery, but still remains an inmate of the asylum. The instrument used was a razor.

Dr. OLIVER exhibited a Thoracic Aneurysm which had caused death by pressure upon the trachea. The aneurysm, about the size of a pigeon's egg, arose from the posterior part of the arch of the aorta; it had incorporated itself with the trachea, causing a distinct bulging in the interior of the trachea just above the division into the main bronchi, obliterating almost the calibre of the tube. The patient was admitted suffering from asphyxia, and Mr. Waldy, then house physician, at once performed tracheotomy, inserting a small œsophageal tube past the aneurysm. The patient lived several hours after the operation. During life there was absence of the ordinary physical signs—viz., bruit and dulness on percussion.—Drs. Philipson and Drummond made corroborative remarks.

Mr. RUTHERFORD MORISON exhibited Cystic Ovaries and Tubes removed by Abdominal Section. The patient made an excellent recovery, in spite of the unsatisfactory state of her health immediately prior to the operation, being extremely blanched from severe hæmorrhages.—Dr. OLIVER gave in detail the medical history of the case, and supported Mr. Morison in his remarks upon the diagnosis and treatment.—Dr. MURPHY, who had also been present at the operation, raised the question as to whether the cysts were not of the class described by Rokitansky.

Dr. DRUMMOND showed a specimen of Tumour of the Pons, secondary to Sarcoma of the Jaw, removed by Mr. Morison seven years previously. The tumour was, like the original, a spindle-celled sarcoma.—Dr. GIBSON raised the question as to the propriety of regarding it in the pathological sense as being *really* secondary.

Mr PAGE read a paper on "Ankylosis of the Temporo-Maxillary Joint treated by Excision of the Condyle." The operation had been most successful, the patient having quite regained the power of movement of the jaw.

Dr. OLIVER read a paper on Recent Advances in Gynæcological Medicine; after which Dr. GIBSON followed with remarks of a very valuable character, contrasting the present with the past treatment of uterine disease, and showing that we were entitled to speak of the present mode as an advance upon the latter.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Oct. 27th, Dr. de Bartolomé, President, in the chair.

Aortic Aneurysm.—Mr. PRIESTLEY showed a specimen of Aneurysm of the Arch of the Aorta bursting into the Trachea, from a patient of Dr. Bartolomé's. He had been a miner and a heavy drinker; no history of syphilis, acute rheumatism, or Bright's disease. Complained only of cough and dyspnœa. Had a double aortic murmur; no area of dulness; no aneurysmal murmur nor pressure symptoms. During a fit of coughing he was suddenly seized with profuse hæmoptysis, and died immediately. Post-mortem: Aortic valves much thickened; aorta undergone calcification; posterior wall had yielded and formed a pouch one inch and a half long, which, pressing on the trachea, had finally burst.

Charcot's Disease of Shoulder.—Mr. RECKLESS introduced this patient, a man aged forty-seven. For eight or nine years he had been the subject of locomotor ataxy. For six months pain had been experienced in the shoulder. He has never had any ataxic symptoms referable to the upper extremity, but when first seen three weeks ago the movements of the left arm were limited to underhand movements. He was markedly ataxic, and was obliged to support himself with his arms whenever he rose from his seat. Patellar reflex was abolished; pupils were extremely contracted, and had the Argyll-Robertson reaction. The left shoulder looked fuller than its fellow; it was flattened under the acromion process, and the finger could be pushed well in under the process. The head of the humerus was plainly visible under the clavicle. On extending and rotating the arm, the head readily slipped into the axilla with a grating noise; it was easily replaced.—Remarks were made by Mr. Garrard and Mr. Atkin.

The Surgical Treatment of Empyema.—Mr. ARTHUR JACKSON read a short paper on this subject, in which he called attention to the method adopted by Ambrose Paré for the management of such cases; how similar it was to the treatment of the present day, and in some particulars almost in advance of it. The various opinions of the great surgical writers, differing as they do on every, or nearly every, essential point, was commented on; and the careful consideration of the results, of interference with the anatomical arrangement of the thoracic cavity by bone forceps, drainage tubes, frequent streams of carbolic acid, and other restless treatment was strongly urged.—The President, Mr. Reckless, Mr. Garrard, Dr. Gwynne, Mr. Pye Smith, Dr. S. Roberts, Mr. Atkin, and Dr. Hargreaves joined in the discussion which followed.

Specimens.—Mr. JACKSON showed a Calculus, removed that day by suprapubic operation. The boy had very crooked legs and distorted pelvis, and the operation performed was indicated as the most suitable. Mr. Jackson also showed a Ruptured Anterior Tibial Artery dissected out, from a case of compound fracture of the leg, followed by gangrene.—Mr. SNELL showed a boy with Dislocation of Lens into Vitreous, of several months' duration. The eye was quiet.

PRIZES FOR ESSAYS ON MEDICO-LEGAL SUBJECTS.—The Medico-legal Society of New York announces the following prizes for original essays on any subject within the domain of Medical Jurisprudence or Forensic Medicine: 1. For the best essay, $100, to be known as the Elliott F. Shepard Prize. 2. For the second best essay, $75. 3. For the third best essay, $50. The prizes to be awarded by a commission, to be named by the president of the Society, which will be hereafter announced. Competition will be limited to active, honorary, and corresponding members of the Society at the time the award is made.

Notices of Books.

Contributions to Clinical and Practical Medicine. By A. T. H. WATERS, M.D., F.R.C.P. Lond., Consulting Physician to the Liverpool Royal Infirmary, late Professor of Medicine in University College, Liverpool. London: J. & A. Churchill. 1887.—We could not notice any book at present more opportunely than this work of Dr. Waters, dealing chiefly with diseases of the chest, and dealing with them as only a physician can who has at once a special aptitude for investigating such cases and a large field of clinical observation and practice. Dr. Waters' authority in such matters is already well known, and the present volume only tends to confirm it. We shall best indicate the nature of the work by giving the title of the chapters:—Chapter 1, Researches on the Temperature in Phthisis and some other Diseases; Chapter 2, Pneumonia (Clinical Lecture); Chapter 3, Bronchitis and other Diseases in the Bronchial Tubes; Chapter 4, On Certain Cases of Lung Disease resembling Acute Phthisis (Clinical Lecture); Chapter 5, On Cancer of the Lungs (Clinical Lecture); Chapter 6, Pleuritic Effusion (Clinical Lecture); Chapter 7, Pleuritic Effusions—their Treatment by Tapping (Clinical Lecture); Chapter 8, Empyema (Abstract of Clinical Lecture); Chapter 9, On Cases of Peri-hepatic Abscess; Chapter 10, On Alpine Winter Climates. The volume ends with a table of 151 cases of pneumonia. It is difficult, and indeed unnecessary, to particularise in commending a work of such great practical value, and which should be a familiar book of reference with practitioners in the great class of common diseases of which it treats. Not the least striking chapter is that on pneumonia. This disease and its treatment have been the subject of much discussion of late years. Few subjects illustrate more strikingly the improvement in medical practice. And few contributions to their illustration are more valuable, or have a firmer basis in experience, than those of Dr. Waters. When we say that of his 151 cases only eleven died we shall have justified these statements. It is still more striking to notice the nature of the eleven fatal cases. No. 7 died from sudden and extensive effusion into the pleura, after convalescence from pneumonia had set in. No. 55 was admitted in a sinking state. No. 81 had evidence of previous phthisis, and a cavity was found in one lung at the necropsy. No. 82 was a woman of worn-out constitution, who sank from excessive diarrhœa. No. 84 had gangrene. No. 109 was admitted in a state of exhaustion, and died within two days. No. 118 was double pneumonia in a very intemperate man, death occurring on the third day after admission. No. 131 was also very intemperate and tubercular. No. 132 was also intemperate. No. 138 was the case of a woman admitted with rheumatic fever with hyperpyrexia. No. 141 died within two days after admission. Such cases and conditions baffle the best treatment; but they do not detract from the significance of 140 recoveries. The favourable tendency of the disease is recognised by Dr. Waters. In no case was venesection used. In twenty cases only was antimony given, and these were twenty of the early number of the series. In the large majority of the cases stimulants (ammonia and brandy) were given. In some cases of debilitated constitution, high temperature, and quick pulse, quinine is considered by Dr. Waters a very valuable agent in pneumonia; externally large mustard and linseed-meal poultices. In every case nutrients are freely allowed. Dr. Waters has seen recovery at nearly eighty years. We have exhausted our space in noticing this important part of the book. But other chapters are deserving of equal attention—notably those on Pleuritic Effusions, and their Treatment, on Cancer of the Lung, on Cases resembling Acute Phthisis, and on Alpine Winter Climates. We advise our readers to study the book for themselves.

Public Health Reports. By Sir JOHN SIMON, K.C.B., F.R.S. Edited by EDWARD SEATON, M.D. Two Volumes. London: J. & A. Churchill.—Few books could be more welcomed by those members of the medical profession and of the public generally, who are interested in the promotion of public health, than these two volumes that have, under the editorship of Dr. Seaton, been issued by the Sanitary Institute of Great Britain. The matter which they embody comes from the pen of a master in his specialty; the writing is always to the point, and often very forcible; and the whole story shows well the steps by which the Public Health Department of the City of London, and later on of the State, was organised and placed on a permanent footing. The work also supplies a great need; for, owing to the small issue of Sir John Simon's annual volumes when he was medical officer to the Privy Council, it has been found impossible by students and others to get access to some of the reports for which there has been great demand. For many years the valuable work on the History and Practice of Vaccination has been out of print, and we are glad to find it reproduced. And when we add that nearly all the principal papers and reports which Sir John Simon contributed during an active career to the subject of public health and preventive medicine are included in the two volumes now published, we shall best have indicated the value which attaches to their issue in the present form. The principles on which Sir John Simon based his teaching and his administration have stood the test of many years' practical experience, and they will at every page be found underlying the advice he has given, whether in relation to our own current preventable diseases, or to those foreign infections which are a source of danger to this country. We would only add that Dr. Seaton has been most successful in his capacity as editor.

The Anatomy of Surgery. By JOHN M'LACHLAN, M.B., M.R.C.S., for some time Demonstrator in the School of Medicine, Edinburgh. Edinburgh: E. & S. Livingstone. 1887.—This work is a great improvement on a former small text-book of Surgical Anatomy written by the same author. It is expressly intended for students preparing for final examinations in Surgery, at which surgical anatomy is required, especially if operations on the dead body form a part (as they always should) of such an examination. Dr. M'Lachlan has now written a very handy manual, clear, precise, and well arranged. The only objections we would make are to the numerals (1) (2) (3) &c., and the letters (*a*) (*b*) (*c*) (*d*) &c., being so freely used as to look like aids to memory rather than facilities of arrangement; and to the title of the book. Notwithstanding the author's special pleading in the preface, we prefer a well-known title like that of Surgical Anatomy to that chosen by Dr. M'Lachlan. The "Anatomy of Surgery" is not justifiable on the same grounds as the titles given to either the "Anatomy of Melancholy" or the "Anatomy of Drunkenness."

Atlas des Maladies de la Peau (Dermatologie et Syphilographie.) Par SILVA ARAUJO, Médecin de la Policlinique Générale (Service des Maladies de la Peau et Syphilis); Membre titulaire de l'Académie Impériale de Médecine. Rio de Janeiro. 1887.—We welcome the first three numbers of this Atlas with great pleasure, and especially at the hands of so earnest and ardent a worker as Dr. Silva Araujo, whose labours on Elephantiasis Arabum and allied affections associated with filariæ are known in this country. This publication is a healthy sign of the earnestness and talent with which dermatology is being studied in a quarter of the globe which cannot but yield valuable results. The text is of much interest, and the adoption of the French language will make the Atlas widely available. The plates (Favus of the Scalp, Tinea Sycosis) are on the whole excellent, but perhaps a little too highly coloured. The third plate consists of phototypes of Elephantiasis Arabum in different stages of cure.

Differential Diagnosis of the Diseases of the Skin, for Students and Practitioners. By CONDICT W. CUTLER, M.S., M.D., Assistant Attending Physician for Skin and Venereal Diseases at the New York Hospital, Out-door Department, &c. New York and London: G. P. Putnam's Sons. 1887.—The intention of the author in this neat little volume is to assist the student and practitioner in making a correct diagnosis by setting before him, in tabulated form, the characteristic symptoms of such skin diseases as are most liable to be confounded one with another. The author has had considerable experience in this kind of work, and has already published a "Manual of Differential Medical Diagnosis." The idea is well carried out, and a careful examination of the text shows us that the different points are mostly well selected, and put in as correct a manner as is possible in a work of this kind.

The Asclepiad. No. 16, Vol. IV.—The most important article in this number is the "Clinical History of Scarlet Fever." Dr. Richardson adduces facts to show that scarlet fever occurs not unfrequently during the first and second years of life, and that the mortality of the disease is really greatest during the period of infancy, if by this term we understand from one to five years of age. The influence of meteorological conditions in relation to scarlet fever is considered, and the conclusion is corroborated that the disease most frequently occurs in autumn. The electrical conditions of the atmosphere do not appear to exercise any appreciable influence either on the frequency or on the fatality of scarlet fever. As to the recurrence of this fever, the author tells us that he himself has thrice suffered from undoubted scarlet fever. He discusses the influence of locality on the fatality of scarlet fever, and the relative mortality of scarlet fever compared with other diseases. Many other points are raised in this excellent article, which concludes with a chapter on treatment, wherein is recommended a gargle of deodorising and healing properties, whose chief constituent is peroxide of hydrogen. "The Physiology of Good and Evil" is in the author's own especial vein. We may quote the following sentences: "The scientific reading of the word *evil* includes the acts and impulses of that lower human nature which my Mentor defines as shaped in iniquity and conceived in sin. This is a necessary part of the theory that man, the highest of the living developments, is an evolution from a lower life, and is a continuous evolution towards something more exalted than himself as he now exists." "John Brown and the Brunonian System" is the title of the Biographical section, with a portrait of this worthy, who flourished in the last century. In the "Opuscula Practica" the question is put: "What is the physiological explanation of being in and out of condition?" The answer given is to the effect that "out of condition" depends on the products of chemical action being retained in the body and causing the nervous centres to lose their activity.

A Handbook of Roller Bandaging. By FANNY E. FULLAGAR. Pp. 24. London: Griffith and Co. 1887.—It is stated in the preface that this *brochure* has been published "with a view to rendering the nurse proficient in the mystery of the roller bandage, and to enable her to refresh her knowledge of those details from time to time." It seems well adapted to the latter purpose, but we doubt the possibility of it accomplishing the first. Proficiency in bandaging can only be attained by constant practice. This is, indeed, well laid down in the concluding paragraph of the handbook: "I would urge upon all who really wish to bandage well to keep up their knowledge by making a point of practising it. Many complain that 'they have no one to practise on'; but surely there can be no difficulty in getting some friend who would not mind having a head, arm, or hand bandaged now and then."

The American Journal of Psychology. Edited by G. STANLEY HALL. November, 1887. Vol. I., No. 1. Baltimore: N. Murray.—This new journal has started well. The first paper in its original department is very good and instructive. It is an article on the "Variations of the normal Knee Jerk, and their relation to the activity of the Central Nervous System." Dr. Lombard is to be congratulated on the intelligent manner in which he has carried out his elaborate research, and also for the suggestiveness of his thoughts. The other original articles are good, but of less interest to medical men. The editor and Yuzero Motoro have written on the "Dermal Sensitiveness to Gradual Pressure Changes." Christine Ladd Franklin's article on "A Method for the Experimental Determination of the Horopter" is of much interest and of considerable ingenuity. "The Psycho-Physic Law and Star Magnitudes," from the pen of Dr. Jastrow, is a learned discussion of a high physiological kind. The second department of the volume on psychological literature is copious and very good, as also are the notes which constitute the third section. If this first number is a foretaste of what is to follow, we feel little doubt of the success of the new psychological journal.

The Transactions of the Northumberland and Durham Medical Society.—This Society is evidently doing good work. The cases recorded and papers published in its Transactions are of considerable merit, and the discussions thereon are interesting and instructive. The list of members of the Society is a long one (173) for a provincial association. The president is Dr. Hume, and the hon. secretaries are Dr. Thomas Oliver and Dr. J. D. Farquharson. Dr. David Drummond, Dr. G. H. Philipson, Dr. Hume, Mr. Black, Dr. Limont, Dr. Mantle, Dr. Oliver, and Dr. Murphy are active members of the Society, which discusses every conceivable topic of medical, surgical, or obstetric interest.

Forbidden Fruit for Young Men. By Major SETON CHURCHILL. Jas. Nisbet and Co.—This little book treats a difficult subject in a thoroughly sensible and dignified manner, a deeply religious tone, devoid of all cant, running through every page. No unnecessary details are given. The writer points out that the difference between those who lead a moral life and those who do not is a difference of self-control, not one of feeling. As other and stronger impulses, such as that of self-preservation, are successfully held in check, there can be, he argues, no reason why the sexual passion should not be controlled. He speaks strongly of the cumulative effects of the sin of unchastity, and how it leads in time to an unsatisfying necessity. He deplores the expensive style of living which modern civilisation has brought about, and looks on this as a great bar to early marriage, and thus a great incentive to immorality. Various excellent practical hints as to diet, abstinence from intoxicating liquors, ablutions, exercise, &c., are given.

Analytical Records.

TOKAYER.

(J. PALUGYAY & SONS, PRESSBURG.)

A GENEROUS and very luscious wine, with fine bouquet and delicate flavour. Its alcoholic strength is that of a wine, but in character it more resembles a liqueur. It contained in 100 volumes—

Alcohol	11·60
Residue obtained by drying at 212° F. ...	25·70
Mineral salts	0·46

The alcohol is equal to 20·3 per cent. of proof spirit. The residue is a syrup, which of course cannot be accurately dried. It contains a very large quantity of sugar.

CHATEAU PALUGYAY—VINUM HUNGARIÆ.

(J. PALUGYAY & SONS.)

A generous natural wine of fine flavour and bouquet, and somewhat high alcoholic strength. Tastes and smells cannot

Digitized by Google

be described in words, but the wine seems to us to resemble some Burgundies. It is certainly unadulterated, sound, and delicate.

Alcohol ... ... (Equal to 23·4 proof spirit.)	13·35
Residue	2·76
Mineral salts	0·223

TOKAYER WEIN.
(J. PALUGYAY & SONS.)

This may be described as a dry Tokay. It will commend itself to all who appreciate the Tokay flavour, but who cannot stand the extreme sweetness of the other brands.

Alcohol ... ... (Equal to 20·6 proof spirit.)	11·80
Residue	2·76
Mineral salts	0·21

VIN DU ROI.
(J. PALUGYAY & SONS.)

This wine resembles the last in flavour and bouquet, but is much less sweet. We found in 100 volumes—

Alcohol ... ... (Equal to 21·7 proof spirit.)	12·40
Residue	11·27
Mineral salts	0·212

FOUNTAIN GROVE—ZINFANDEL.
(LAY CLARKE & CO., SANTA ROSA.)

This is a good, sound, unfortified, and unadulterated wine. Partial analysis gave the following quantities in 100 volumes:—

Alcohol ... ... (Equal to 22·4 proof spirit.)	12·75
Residue obtained by evaporation at 212° F.	2·77
Mineral salts	0·223

ROWNTREE'S HLECT EXTRACT OF COCOA.
(H. J. ROWNTREE & CO., YORK.)

This is a strong and pure cocoa extract. It contains no added starch or sugar, and is easily soluble, or rather miscible, even with cold water. It is free from acrid taste, and deserves commendation.

SALT REGAL.
(FRITZ & CO., CASTLE-STREET, LIVERPOOL.)

This is a curious preparation, and one upon which we are unable to give a decided opinion. It appears to be an effervescent saline aperient mixture, and it also contains alkaline permanganate, as is shown by the absorption spectrum and by chemical tests. But it also contains some other ingredient, probably belonging to the aromatic series, which gives a broad absorption band and fluoresces when treated with potash.

New Inventions.

BALLIN'S IMPROVED FUR RESPIRATOR.

THIS invention consists of a simple piece of fur lined with Welsh flannel, and it certainly possesses the merit of effectually warming the inspired air, besides being sightly and light. The only objection that occurs to us is in the liability of this material to become laden with dust and other impurities abounding in a fog-laden atmosphere, and the difficulty in ensuring a sufficient amount of cleanliness. At the same time, no respirator is free from such drawbacks, for which the wearers have an obvious remedy. The makers are Maw, Son, and Thompson.

"THE HYGIENIC PROTECTOR UNDER-VEST."

A SPECIMEN of the above article of clothing has been submitted to us for our opinion of its value. Undoubtedly it is of great importance that the lumbar and abdominal regions should be well protected from chills, which are apt to be encountered in such a variable climate as ours. And this end seems to be conveniently and efficiently secured by this under-vest, which, made of the finest wool, is provided with an extra layer at that part which covers the loins and abdomen, and so renders an independent bandage unnecessary. The patentee is Mr. J. S. Wells, Nottingham.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

FRIDAY, NOVEMBER 25TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

THE Council proceeded with the consideration of the case of Mr. Allbutt. At the last sitting of the Council, Mr. Robert Lamb Wallace, appearing for Mr. Allbutt, had concluded his address on behalf of his client.

The PRESIDENT asked what was the wish of the Council as to the admission of strangers during the further progress of the case.

Dr. AQUILLA SMITH said the proper course was that strangers should withdraw, and such explanations as Mr. Muir Mackenzie had to give ought to be reserved for the Council. He moved that strangers should withdraw.

Dr. LEISHMAN seconded the motion. Anything that Mr. Muir Mackenzie might have to say would not be so much in the form of reply as in that of advice.

Sir W. FOSTER said that the Council, who were in the position of a jury, had heard the case of Mr. Allbutt argued in public, and it was only right that the reply to that argument should also be made in public.

Dr. HERON WATSON could not admit that the Council occupied the position of a jury. They were the judges. They had heard a statement of the case made, and required no argument with reference to the arguments which had been laid before them further than that they might require advice upon any legal point in coming to a conclusion with regard to their sentence. He should support Dr. Smith's motion.

Dr. HUMPHRY said the position was this: Arguments in favour of Mr. Allbutt had been laid before them, which arguments would of course go before the public, and it was only right that their own counsel should have an opportunity of answering before the public such of those arguments as he might think right. The case would come imperfectly before the public unless that course was adopted, and it was therefore exceedingly desirable that strangers should be present to hear any reply which Mr. Muir Mackenzie might intend to make.

The motion was put to the Council, and declared to be lost.

Mr. MUIR MACKENZIE then addressed the Council, and in doing so he said he should, subject to any directions he might receive, confine himself simply to his functions as a lawyer, and not attempt to comment upon any questions of fact which had arisen during the inquiry. This matter arose under the 29th section of the Medical Act of 1858, which provided that if any registered medical practitioner should, after due inquiry, be adjudged by the General Council to have been guilty of "infamous conduct" in any professional respect, the General Council might direct the Registrar to erase the name of such medical practitioner from the Register. The matter brought to the attention of the Council in this case was the publication by a registered medical practitioner of a book entitled "The Wife's Handbook," and in the terms of the notice given to Mr. Allbutt it was stated that information had been laid before the Council by which he was charged with having been guilty of "infamous conduct in a professional respect"—viz., that he, being the author of this book, "did print, publish, and publicly sell, or procure to be printed, published, and publicly sold, copies thereof in London and elsewhere at so low a price as to bring such work within the reach of youth of both sexes, to the detriment of public morals." At the very outset of the inquiry a very important question arose, and one upon which there might be a great deal of argument—

Digitized by Google

viz., whether the publication of a book in this way was "infamous conduct in a professional respect" which came within the cognisance of the Council at all. It might be suggested that it was only the conduct of a medical practitioner towards a patient, or, as had been said, the case of a solicitor towards a client. Any question of that kind as to the competency and the duty of the General Council to judge upon this question was, he thought, fully set at rest by the decision of the Queen's Bench in the case of *ex parte* La Mert, decided in 1863. In that case the question was whether the General Council had jurisdiction to remove the name of a practitioner from the Register for publishing a book which the Council had adjudged to be an immoral and indecent publication. In that case the Council removed the practitioner's name from the Register, and then an application was made to the Queen's Bench for a mandamus to the Council to restore the name to the Register on the ground that they had no jurisdiction to entertain the question. It appeared from La Mert's evidence that he received a letter from the Registrar of the Council communicating a statement committed for their consideration, purporting to show that he had been guilty of "infamous conduct in a professional respect" "in publishing or causing to be published an indecent and unprofessional treatise, entitled 'Self-preservation, a popular treatise on the Cure of Nervous and Physical Debility.'" On receipt of this letter, Mr. La Mert applied to be heard by counsel, but that was refused under the then bye-laws, and he was informed that he would be heard either by himself or his solicitor. He thereupon wrote an answer to the charge, which was laid before the Council, and in the result the Council passed a resolution erasing his name from the Register. It was contended on behalf of the applicant that he had not been guilty of "infamous conduct" in any "professional respect," and further that there had been no due inquiry as to the allegation made against him. Lord Chief Justice Cockburn, in giving the judgment of the Court, said, "We are all agreed that Section 29 of the Act makes the Medical Council the sole judges whether a medical practitioner on the Register has been guilty of 'infamous conduct in any professional respect.' They have decided that the applicant has been guilty of such conduct in respect of the publication of this book. The Legislature, considering them the best judges in such a matter, have left the matter in their arbitrament, and therefore we cannot interfere." The proceedings in that case were initiated precisely as in the present case—namely, by a letter communicating to the Council the publication of a treatise which it was alleged was indecent and unprofessional. The Council under its then procedure erased the name of the practitioner from the Register. The point was taken before the Court that this particular class of offence did not come within Section 29, and the judges, giving the widest interpretation to the section, said it was the intention of Parliament to make the Medical Council the sole judges whether the publication of such a treatise was or was not "infamous conduct in a professional respect." Since that decision there had been certainly one, and he believed other cases, in which the Council had acted upon it, and in the face of that decision he advised the Council that it was not only within their competency, but their bounden duty, to inquire whether in their opinion this treatise was, to use the words quoted in that case, "indecent and unprofessional." As to the advisability of the Council exercising jurisdiction of this kind, he pointed out that since the Act of 1858 the Legislature had, in the only way in which it could, signified its approval of the exercise of this jurisdiction by the Council, for by the Act of 1878 the powers of the Council were extended to the Dentists' Register. The very words of the section were also used in an Act of Parliament passed in 1874, which gave jurisdiction to the Society of Apothecaries to remove licentiates from their body on the same grounds, and if it was thought that the exercise of this domestic jurisdiction was in any way inexpedient, the Legislature had the whole constitution of the Medical Council under its review in 1886, and yet by the Act of that year they did not in any way touch the judicial power which the Council enjoyed. That being so, there was only one question for the Council to determine—which, perhaps, might be subdivided into two parts: whether the practices described as inculcated in Chapter 7 in the publication entitled "The Wife's Handbook" were calculated to promote immorality; and whether Mr. Allbutt, in publishing this book, was guilty of "infamous conduct in a professional respect." That was the sole issue for the Council to determine, taking, of course, the book as a whole. These were questions of fact, and must be decided wholly without reference to any attacks that had been made upon the person who had brought the matter before the Council; and of course it would be remembered that the person on whom those attacks were made was not before the Council, and had had no opportunity of making any statement to controvert them. He should not be so impertinent as to discuss any matter connected with questions of fact dealt with in the work itself, because that was a matter peculiarly and exceptionally within the province of the Council, and one which the Legislature had deputed to them alone as the supreme judges of what was or was not professional misconduct. With reference to the article in the *Fortnightly*, which was written by Mr. Montague Cookson, he said it might be in the recollection of those who read that article that it raised a question open to a great deal of criticism as to whether it was wise to treat such matters in the columns of public journals; that, however, was immaterial, but he would read one passage, and what he thought must be the only passage to which Mr. Wallace would have referred in suggesting that any part of that treatise had any sort of similarity to the book which was now being discussed. The subject of Mr. Cookson's treatise was "The Morality of Married Life," and he said at the end of the paper, after having called attention to the miseries resulting from improvident marriages: "The object of this paper would be greatly misunderstood if it were thought that I intended to propose any panacea for the many ills of the times. My aim is much more simple—namely, to point out that the conditions of our existence are far more elastic than is commonly believed. I hold that this elasticity consists in the limitation of the number of the family by obedience to natural laws, which all may discover and verify if they will, and that such limitation is as much the duty of married persons as the observance of chastity is the duty of those that are unmarried. One of the main wants of the day is, as I conceive, the formation of a sound public opinion on this subject. Once started, it would gather force rapidly, and at last effect a social revolution of the highest importance—a revolution of which the course would not be traced in blood or riot, but in man's moral, intellectual, and material growth. The change cannot take its rise in that quarter where it would yield the most beneficial results—amongst the lowest strata of the English people. It must begin, in the first instance, with those above them, and, indeed, with the most educated of these. Let men co-operate to this end, and the opinions here expressed will soon ripen into a creed, which will be the watchword of no sect or party, will fetter no freedom of thought, but be accepted as God's later teaching to His creatures, and a symbol of common devotion to the welfare of humanity." It was really asking too much of the credulity of the Council to ask them to compare such a passage as that with the passages in the book which Mr. Farrer, in his opening of the case, had read to the Council. Moreover, it was a strange argument to ask the Council to withhold its judgment in this case, in which they were inquiring into the conduct of a medical practitioner under the section of the Act, because the Council had not thought fit to prosecute Mr. Montague Cookson, who was not a member of the profession, for publishing that article.

Strangers were then directed to withdraw. On their readmission,

The PRESIDENT stated that the Council had agreed to the following resolutions:—"That in the opinion of the Council Mr. Henry Arthur Allbutt has committed the offence charged against him—that is to say, of having published and publicly caused to be sold a work entitled 'The Wife's Handbook,' in London and elsewhere, and at so low a price as to bring the work with the reach of the youth of both sexes, to the detriment of public morals. That the offence is, in the opinion of the Council, infamous conduct in a professional respect. That the Registrar be hereby directed to erase the name of Mr. Henry Arthur Allbutt from the Medical Register."

THE CASE OF MR. H. F. PARTRIDGE.

The REGISTRAR stated that Mr. Partridge had been summoned to appear before the Council on that day, but did not appear either in person or by any representative.

Mr. WHEELHOUSE moved, and Dr. MATTHEWS DUNCAN seconded, that the report from the Dental Committee in

Digitized by Google

regard to this case be received and entered in the Minutes. This motion was agreed to.

Mr. FARRER stated that in this case the Council had on June 2nd, 1886, directed the erasure of Mr. Partridge's qualification and name from the Register. There was an undoubted power in the Council under the Medical Act of 1858 to withdraw names from the Medical Register where all the qualifications had been taken away; but, unfortunately, this by some oversight was not repeated in the Dentists Act. Mr. Partridge subsequently applied for a mandamus to restore him to the Register, and this was granted on June 15th last on the ground that his case had not been decided on the merits of the case. That decision was affirmed on appeal, and Lord Esher, in delivering the judgment of the Court, said that although the mere fact of a person having broken that which he undertook to do with his local authority, and having been in consequence struck off their Register, did not entitle anybody to strike him off the Register without inquiry, yet these facts brought him within the jurisdiction of the Medical Council, and if they were of opinion that what he had done was disgraceful in his professional capacity—and he should say himself that a deliberate and persistent breach of this obligation would be disgraceful conduct, upon which they might come to the conclusion that he had been guilty of disgraceful conduct—then, after giving him the opportunity of being heard before them, they might erase his name from the Register. Lord Esher therefore not only suggested but encouraged, and almost called upon the Council to consider the case on its merits. The Report of the Dental Committee contained the following statement of fact:—

"The name of Henry Francis Partridge, with the qualification of Lic. Den. Surg. R. Coll. Surg. Irel. 1878, was placed on the Dentists' Register on December 20th, 1878. He did not claim registration on account of his having been in practice before the passing of the Dentists Act, and cannot now be registered as having been in practice at the passing of that Act. On July 2nd, 1885, the Royal College of Surgeons in Ireland withdrew or cancelled the diploma granted by them to Partridge, and a letter dated July 4th, 1885, notifying that fact, was addressed by the Secretary of the Council of the Royal College of Surgeons in Ireland to the Registrar of the General Medical Council, and at a meeting of the Executive Committee on July 10th, 1885, it was resolved that the Registrar be directed to make application to the Royal College of Surgeons in Ireland for information as to the cause of withdrawal of the diploma. The President and Council of the Royal College of Surgeons in Ireland withdrew or cancelled the diploma of Mr. Partridge because of his having, in violation of his undertaking given to that College, attracted business by advertising in connexion with the Ladies' Dental Institution, South Kensington. At a meeting of the General Medical Council held on June 2nd, 1886, it was decided as follows:—That the qualification of H. F. Partridge be erased from the Dentists' Register; that the name of the said H. F. Partridge be also erased from the Dentists' Register. The Ordinances of the Royal College of Surgeons in Ireland forbid advertising, and Mr. Partridge, both before his admission to examination for his diploma in Dental Surgery, and again after passing his examination, and before he obtained his diploma, signed a declaration that so long as he held such diploma he would not attract business by advertising or any other practice considered unbecoming by the College, and agreed that his diploma should be cancelled on its being proven that he had done so. Mr. Partridge has broken such pledge by advertising whilst he was still holding the said diploma, and he did so after repeated warnings from the College. And, further, in answer to the first of such warnings, he apologised, and stated that he was willing to comply with the laws of the College. On June 15th, 1887, the High Court of Justice, at the instance of Mr. Partridge, granted a mandamus to the General Medical Council to restore his name to the Register of Dentists. On August 1st, 1887, on appeal by the General Medical Council, such decision was confirmed, and the mandamus directed to issue. The name and qualification of Mr. Partridge have been restored to the Dentists' Register pursuant to such mandamus. Mr. Partridge still continues to advertise."

Mr. PARTRIDGE, though not appearing in person, had sent in a written statement in which he stated that at the time of signing the arbitrary contract imposed upon him—namely, not to advertise—he did not anticipate being visited with blindness, neither did he think any objection would have been taken to his advertising his institution on precisely the same principles as medical men advertised self-supporting homes &c. He denied that his advertisements could be described as "disgraceful." He was at a loss to understand the object of the present inquiry, having thought that the question had been finally settled, and his obligation fulfilled by returning his diploma. He regretted having violated his undertaking with his College, but no other course was open to him. Considering that he had been in the profession for nearly a quarter of a century, long before the Act of Parliament or the Register was ever dreamt of, he thought the treatment to which he had been subjected was exceedingly arbitrary, amounting to persecution.

Mr. FARRER explained that the question before the Council was not that of advertising, but whether Mr. Partridge had behaved disgracefully in violating the undertaking which he gave to the College of Surgeons of Dublin.

The Council then deliberated in private, and on the readmission of strangers,

The PRESIDENT said the Council had agreed to the following resolutions:—"That, in the opinion of the Council, Mr. Henry Francis Partridge has committed the offence charged against him—that is to say, wilfully violated the declaration made and subscribed by him, whereby he declared that as long as he held the diploma in dental surgery of the Royal College of Surgeons of Ireland, he would not attract business by advertising or any other unbecoming practice. That the offence is, in the opinion of the Council, disgraceful conduct in a professional respect. That the Registrar be directed to erase the name of Henry Francis Partridge from the Dentists' Register.

THE APOTHECARIES' SOCIETY AND THEIR DIPLOMA IN PUBLIC HEALTH.

With reference to the motion brought before the Council by Mr. Carter for the registration of the Diploma in Public Health of the Apothecaries' Society of London, upon which it was resolved on the motion of Dr. Heron Watson to take counsel's opinion, Mr. Muir Mackenzie now stated that in his opinion the Apothecaries' Society of London was not a body that could in accordance with the Medical Act (1886) grant a diploma in Public Health.

With the permission of the Council the motion made by Mr. Carter on this subject was withdrawn.

FOREIGN DEGREES.

Dr. HUMPHRY moved the adoption of the report by the Committee on the evidence which should be required in regard to foreign medical diplomas presented for registration by registered medical practitioners. The committee recommended that the Registrar should be authorised to register the several degrees of those applicants who had complied with the requirements of the Council, and that any incomplete applications, when made complete, and also all future applications, should be submitted either to the Council or to the Executive Committee, the results in the latter case to be reported to the next meeting of the Council. The fee to be charged for the registration of superadded foreign degrees should be £2. A number of applications had been received from registered practitioners for the registration of colonial degrees as additional qualifications, but in the opinion of the committee such degrees were not registrable under Section 16 of the Medical Act (1886), which mentioned "foreign" degrees only. They might hereafter become registrable in the future Colonial Register.

Dr. QUAIN seconded the motion, which was agreed to.

The Council then adjourned.

SATURDAY, NOVEMBER 26TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

THE EXPENDITURE OF THE COUNCIL.

Mr. WHEELHOUSE moved that the report from the Income and Expenditure Committee be received and entered on the Minutes.

Dr. HUMPHRY seconded the motion, which was carried.

The report stated that the committee had already in their interim report, dated May 12th, 1887, stated the items of income and expenditure of the Council, and indicated the necessity for a reduction of the expenditure, expressing the opinion that this would be best effected by lessening the expenses attendant upon the meetings of the Council. The committee deferred, however, making any proposal as to the method of effecting that reduction until the report of the Pro-

Digitized by Google

cedure Committee should have been considered by the Council. By the increase of the number of members of the Executive Committee from six to eight, the total annual expenses of that committee would be increased by about £100. The report continued: "It is hoped that by the addition to the numbers of the Executive Committee, and the increased duties imposed upon it, as well as by the appointment of the Education and the Examination Committees, the transaction of the business of the Council will be facilitated, and the time of the Council will be proportionately saved. Still, it is too soon to express a confidence that the expenses attendant on the meetings of the Council will in the future be materially reduced. Hence, with a view of to some extent reducing the expenses of the meetings of Council, the committee recommend—1. That the allowance to members for travelling expenses should in future be the amount approximately paid by them according to the following tariff, instead of according to the present method of payment. This alteration will affect a saving of about £50 at each meeting of the Council, and a corresponding diminution at each meeting of the Executive Committee and of the English Branch Council.

Table showing Data in regard to Travelling Allowances to Members of Council.

No. of Members.	Place.	Return Ticket.	For what time available.	Suggested Amount to cover Return Fare and Sundry Expenses.	Present Amount allowed.
1	Aberdeen ...	£8 13 6	1 month	£7 7 0	£9 9 0
1	Birmingham ..	1 13 6	1 month	2 2 0	3 3 0
1	Cambridge ...	0 15 10	1 month	1 1 0	2 2 0
1	Dingwall ...	7 10 0	1 month	8 8 0	9 9 0
7	Dublin	4 15 6	1 month	5 5 0	8 8 0
3	Edinburgh ...	5 9 6	1 month	6 6 0	9 9 0
3	Glasgow... ...	5 10 3	1 month	6 6 0	9 9 0
2	Leeds	2 11 6	Unlimited	3 3 0	4 4 0
1	Liverpool ...	2 18 0	Unlimited	3 3 0	4 4 0
1	St. Andrews ...	6 1 9	1 month	7 7 0	9 9 0

2. That any member of a Branch Council residing more than two hundred miles from the place of meeting of the Branch Council shall receive a fee for the day of going to and also for the day of returning from the meeting, in addition to the fee for the day of attendance. 3. That the above tariff for payment of travelling and recommendation for payment of members of Branch Councils should come into operation with the new year. The committee have considered the question of the reduction of the fee paid to each member of the Council for attendance at the meetings of the Council, but, while they feel that the question of the reduction of the fee may arise in the future, they are not prepared, at present, to make a recommendation on the subject. With reference to the recommendation of the Executive Committee of date July 25th, 1887 (Vol. xxiv., p. 354, Clause 4c), that the Registrar's salary be increased by £100 yearly, the committee, having in view the general question of the future expenditure of the Council, are not prepared at present to recommend an increase of more than £50 a year."

Sir W. FOSTER moved the adoption of the report. It was somewhat extraordinary that this motion should not have been made by the chairman of the committee.

Dr. HUMPHRY said he could not the least in the world commend the report to the Council. He was not very proud of his name standing at the head of it. (Hear, hear.) It did so stand because, as chairman, he was bound to submit the results of the committee to the Council, but he should be only too glad if the Council referred the thing back again to the committee. He did not think it was at all an adequate report.

Mr. TEALE having seconded its adoption,

Dr. AQUILLA SMITH moved as an amendment that it be considered paragraph by paragraph.

Dr. QUAIN seconded the amendment, which was put to the Council and lost by eleven votes against ten.

Dr. LEISHMAN then moved a second amendment, "That the report by the Income and Expenditure Committee be referred to that committee for further consideration." His objection to the report as a whole was the small result which seemed to have ensued from the deliberations of the committee. It reminded him of a man who, having been possessed of considerable means, resolved himself into an income and expenditure committee in order to consider how he could best reduce his expenditure, and, after very mature consideration, he came to the conclusion that the only way in which he could diminish it, the excess being some thousands of pounds, was by giving up *The Times* and taking in the *Daily Telegraph*. (Laughter.) The only point in the diminution of expenditure made in the report was in an item in which there was really no excess. It was quite true the travelling allowance to members coming from a distance was in excess of the actual railway fare, but the hotel allowance was considerably less than would be spent without the least extravagance in a good London hotel, and therefore, taking them together, the actual expenditure was about balanced. He had not the slightest objection to diminish this allowance, but there were other directions in which the report might have given useful information. The Council would have done well if they had adopted as their text what their friend Dr. Quain very frequently pressed upon them—viz., that time was money (hear, hear), and if anything was to be done to reduce its expenditure, it would be by an economical and careful expenditure of its time. He thought, looking to the increased number of powers of the Executive Committee, that a second meeting of the Council in the course of the year need only be had recourse to under exceptional circumstances.

Dr. HERON WATSON seconded the amendment.

The amendment having been supported by several members of the Council,

Dr. HUMPHRY thought Dr. Leishman's proposal might be accepted without further discussion. (Hear, hear.)

Dr. HERON WATSON said it would be of great advantage to the committee to hear the remarks of as many members of the Council as possible, so that they might be assisted in coming to a conclusion when they brought up the report.

Dr. QUAIN said that there were many other points that had been brought before the committee, but they were deferred until the results of the suggestions made by the Procedure Committee had been seen. Those points were the diminution of the frequency of the meetings of the Council; that the daily meetings of the Council should be five hours instead of four; that the allowance to members for travelling expenses should be the amount actually paid by them instead of fixed sums as at present; that the fee of five guineas allowed for each day's allowance at meetings should include hotel expenses, whereby a total annual saving of about £500 would be obtained; and that luncheon should no longer be provided at the expense of the Council, whereby a saving of at least £100 a year would be effected. It was also recommended that the General Council's fees should not in any one year exceed £1700. He hoped that, if the Council did not adopt the whole report, they would at any rate accept the second and third recommendations, which were only a matter of justice to the members of the Branch Councils.

Dr. HUMPHRY was very disappointed that the committee had only been able to arrive at results so utterly inadequate to meet the real circumstances. He thought that far too great an amount of money had all along been expended upon the meetings of the Council; money which might have been appropriated in other ways for the benefit of the profession, and not simply put into their own pockets. The expenses of the Council for this year would be about £3000, which was a great deal too much. It must also be remembered that the income would probably not increase, whilst the expenses would be increased by about £1000 annually for the inspection and visitation of examinations, in accordance with the resolution of the Council. He could not see his way to doing away with the November sitting; but, on the other hand, he should be glad to see the payment to members reduced, or even that there should be no payment at all. The Council would then be in a much better condition.

Dr. TUKE agreed that the idea of reducing the number of their meetings was entirely utopian, and that the only way in which they could legitimately reduce the expenditure was by a reduction of the fees paid to members. The fees paid were at once too small and too great: too small, inasmuch as they did not represent in any way the loss which the large proportion of the Council sustained in attending its meetings; and too great, looking to the revenue of the Council. He hoped that the committee would take into consideration whether it would not be a wise and proper method to give up these fees altogether, for any smaller reduction would be ridiculous under the circumstances. He also suggested that it would be a proper thing to recommend that the various corporations who sent repre-

Digitized by Google

tatives to the Council should be asked to bear some amount of the expenses.

Sir WALTER FOSTER was very glad to see the universal desire for economy that had been developed in the gentlemen representing the corporations. For years past they had been receiving their hundreds a year, but having been overtaken by a sense of their past conduct (laughter) they were now anxious that the profession should reap more benefit from the money that had been obtained from them for registration purposes. He congratulated the Council upon that happier condition of mind, though he was sorry it had come so late. With reference to the fees themselves, he was not acquainted with any body that was not paid that gave the same average attendance that was given at the Council; and there was this advantage in paying members—that it increased their sense of responsibility. He was not, therefore, in favour of absolutely giving up the fees. He was, however, in favour of giving a harder day's work for the money received, and suggested that the Council should sit from 10 A.M. to 1 P.M. and from 1.30 to 6 P.M., for in that way they might reduce the number of Council meetings very considerably, and so reduce the expenses. Another reform that might be introduced was this—that the constituent bodies of the Council should pay their own representatives.

Dr. STRUTHERS thought the £5 5*s.* a day might be reduced to £3 3*s.*, and that at any rate the meetings might commence an hour earlier.

Mr. MCVAIL supported the suggestion that the Council should meet at ten in the morning, for in that case the business which had extended over five days might have been finished in two.

Mr. MITCHELL BANKS also supported this suggestion. He had no objection in the world to every reasonable cutting down of fees, but he believed the public would not grudge any reasonable expenditure providing they got a proper amount of work.

Dr. HAUGHTON, as a member of the committee, wished to state that the committee did consider a number of the suggestions that had been made, and, amongst others, the most important question raised by Sir Walter Foster, which, he thought, was the real solution of their difficulty—namely, that the corporations and other bodies should pay their own representatives. He should support Dr. Leishman's proposal to send the report back to the committee for further consideration.

Dr. HERON WATSON said if the reduction of fees was deemed to be necessary he would agree to it, but he would rather do away with them altogether. Five guineas a day could in no way represent the loss to gentlemen round that Board, and by doing away with them altogether they would at the same time do away with an allegation—which he regretted to think had again and again been made public in some papers,—that the Council sat there for a long session for the purpose of pocketing a miserable fee. The recommendation that they should sit more than four hours a day was a valuable one, but he could quite understand that to gentlemen residing in London who were members of the Council it was a matter of extreme difficulty to arrange this, and some consideration should be given to their requirements.

The PRESIDENT said there was not a single suggestion made that had not been previously considered, and on which there was not something to say on both sides. He was sure, however, that the discussion had been extremely valuable, and he hoped that through it they might see a way to diminishing the expenses of the Council.

The amendment was then put and agreed to, and on the motion of Dr. QUAIN, Professors Macnamara and Leishmann were added to the committee.

On the motion of Dr. QUAIN the Standing Orders were suspended for the consideration of two of the recommendations in the report with reference to the payment of members of Branch Councils and to the increase in the Registrar's salary.

It was then moved by Sir WALTER FOSTER, seconded by Dr. PETTIGREW, and agreed to: "That any member of a Branch Council whose duty in attending such Branch Council involves absence from home of more than one day, shall receive a fee for each day so occupied." Dr. QUAIN moved that the Registrar's salary be increased by £50 a year, in accordance with the recommendation in the Report, and in doing so called attention to the fact that scarcely a week passed in which the London members were not called upon to act on behalf of the Council. That was a matter that ought to be taken into consideration.

Dr. STRUTHERS moved as an amendment: "That the increase of the Registrar's yearly salary be £100 per annum, as recommended by the Executive Committee."

Dr. BANKS seconded the amendment, which was put to the Council and carried.

It was moved by Dr. PETTIGREW, seconded by Dr. MATTHEWS DUNCAN, and agreed to: "That the nomination by the Scottish Branch Council of Dr. J. Batty Tuke as a member of the Education Committee be approved."

It was moved by Mr. TEALE, seconded by Dr. QUAIN, and agreed to:—"That it be referred to the Executive Committee to consider under what circumstances a registered medical practitioner would render himself liable to the censure of the Council in reference to the employment of unqualified assistants."

It was moved by Dr. STRUTHERS, seconded by Dr. BANKS, and agreed to: "That the opinion of counsel be obtained in regard to Section 21 of the Medical Act (1886), as to whether the person to be examined for the diploma referred to in the section must be a registered practitioner before being admitted to the examination."

The Registrar called attention to the fact that, on the first day of the present session, he had laid on the Council table proof sheets, from 1 to 256, of a general index to vols. i. to xxiii. (inclusive) of the Council's Minutes, which he had for some time had in preparation, and that to these proof sheets he had prefixed a note indicating that they were submitted for the purpose of showing members of the Council the form in which this index is drawn up, and of soliciting from any of the members suggestions for the correction or improvement of the index.

This concluded the business of the Council.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

THE autumn general meeting of this Association took place on Wednesday, Nov. 23rd, at 49, Berners-street, London, Sir Thos. Crawford, K.C.B., Director-General, A.M.S., President, in the chair.

The Council reported further proceedings with reference to the exclusion of those holding Irish medical degrees and the higher diplomas of the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland from English hospital appointments.

Professor Yeo, on behalf of the Council, moved (1) that the name of a newly elected member shall not be entered on the roll until the first subscription be paid; and (2) that the second paragraph of Rule 11 be altered, so as to read as follows: "There shall be two other Association dinners each year, at such times and places as the Council may determine."

The Secretaries reported that the number of members in the Association had now reached 515.

A vote of thanks to the President for his assiduous and valuable services to the Association was proposed by Professor Yeo, seconded by Dr. Jones, and carried unanimously. A vote of thanks to the General Apothecaries' Company for the use of their premises was also passed.

In the evening the Association dined at the Holborn Restaurant, Sir Thomas Crawford in the chair, and Sir B. W. Foster, ex-president, as vice-chairman. A telegram was received from Dr. Bridgewater, President of Council of the British Medical Association, regretting his being unable to be present as a guest. After the usual loyal toast, the President proposed "Our Guests," which was responded to in witty and happy terms by Professor Pettigrew, F.R.S., and Dr. M'Vail (Glasgow), members of the General Medical Council. Dr. Macnaughton Jones then proposed the toast, "The Universities and Licensing Bodies," coupling with it the name of Professor MacAlister of Cambridge (President-elect of the Association). The toast of the evening, "The Irish Medical Schools and Graduates' Association," was ably given by Professor Struthers of Aberdeen; and Professor Jacob of Dublin replied. Professor Humphry of Cambridge gave "Our Chairman," in his usual graceful and eloquent way. The proceedings were varied and enlivened by songs, sung by Messrs. Payne and Baly and Dr. Macan.

THE LANCET.

LONDON. SATURDAY, DECEMBER 3, 1887.

IN the last three issues, in the most prominent position of this journal, we have directed attention to a new feature of medical teaching under the seemingly harmless guise of popular literature. We have marked with sorrow and with indignation the action of some even of our personal friends in the profession in lending the authority of their status as qualified medical men to a practice which, however specious or well intended, is at once discreditable to its promoters and injurious to the general public. We refer, of course, to this latest departure in cheap journalism, which aims at instructing each and any reader, without distinction, in the details of disease and its treatment, apparently without regarding the fact that such instruction is in truth illusory, since it must be very partial, and may consequently at any point in its practical application result in serious mischief. We know that it may be contended by the promoters of this work that there are matters with which the physician has to do which also lie within the sphere of domestic management, and may therefore serve him as a text for popular disquisitions. The general truth of this argument no one will dispute, and we do not. There are subjects connected with the hygiene of the nursery, the school room, the kitchen, and the house generally, which are everyone's concern, and which by a natural process inevitably tend to diffuse themselves into the common stock of human knowledge (although it must be remembered that the medical attendant of the family can be consulted on these matters and is fully capable of giving reliable advice). All this we freely allow, and we can well believe that those of our medical brethren who appear for the time being to dissent from us in the present discussion imagine that these round terms describe the true position with regard to this matter. We wish in the most distinct and emphatic manner to warn them that it is not so. It is when we come to the enunciation of details, when we actually view in conjunction the human body and the external influences, healthy and unhealthy, to which it is subject, that the responsibility of using or misusing knowledge is clearly seen. We are then conscious of standing upon a borderland in ethics, ethics not of our profession merely but of the immeasurably wider society of mankind. We then see that it is one thing to expound in public the principle of healthy living, but quite another to assume the office of popular instructor in the treatment of disease. Physical perversion, like moral perversity, can only be effectually reckoned with on intimate acquaintance. It surely follows, accordingly, that those who reason otherwise in practice, and avow that matters of practical therapeutics can be rightly offered to and accepted by an ignorant or partially instructed [redacted] is the lesser evil), but of what, [redacted] an offence of the most [redacted] well-being, [redacted] to which we have referred two have appeared during the past month, both professing to contain articles written upon "Health and Disease" by well-known practitioners in medicine. Another cheap paper which has been in existence some few months, and was originally promoted from philanthropic motives connected with the medical charities of this metropolis, has been slowly drifting into that course which we condemn, and has become the medium of an attempt to popularise medicine. We may add that when this paper first appeared we most cordially approved of the work which it was intended to perform, and testified as much in our columns. It has now, however, changed its sub-title, and has openly avowed its intention to teach the practice of medicine. How much philanthropy has to do with this new departure we must leave others to determine. The literary contents of the paper to which we refer are of the most heterogeneous character. Sermons, discourses on physiology, palmistry, bacteriology, enigmas, fever, *food*, Ruskin, vaccination, the action of remedies in disease—that hunting ground of adventurous empirics,—serial stories for young people, microbes, puzzles, and acrostics, are blended week by week in one incongruous whole. There is a "pulpit" for the oracles of medicine, a corner for hospital matrons, a children's corner, and a whole page which acts as an advertising handbill, in which, without permission, for they dared not give it, the names, titles, official addresses, and special departments of the staff of almost every hospital in London are cornered, so to speak, in a body—penned, as it were, for selection by a supposed discriminating and astute non-professional public, to the professional injury of all those whose names do not appear in the list—a startling matter indeed. For the paper is not a medical production. True, it contains articles on medicine and surgery, but these are half buried, as we have shown, among puzzles, novels, and songs; and the sum of all this matter presents itself as a means of interesting and instructing—whom? Not "practitioners" merely, but along with them families, parishes, clergy, congregations, and that illimitable body the charitable public. Let the object of this penny paper be what it may, we cannot in duty do less than describe it as a striking presentation of cleverness divorced from wisdom in its endeavour to transfer the solid realities and responsibilities of medical treatment from those who can understand them to those who cannot.

A later issued periodical is one of a like stamp with its fellow, and is, we suspect, an offshoot from the one to which we have just referred. It is younger, smaller, and, as one would naturally expect, is as yet hardly so confident in its advances. Progressing step by step, it but feels its way so far, and babbles somewhat for a serious effort in medical teaching; but it, like its neighbour, bears in front the hard and brazen polish of advertisement, disclaimed and yet allowed, and shines in all the glory of papers contributed or promised by owners of titles conferred by corporate authorities in medicine and surgery, who are thus, without leave asked, assumed as its sponsors. Under this patronage, unwilling though it be, and a lay editorship we find reproduced in a milder form the same congeries of professional information, with children's songs, cookery receipts, remarks on emotion, and infantile jokes. As yet there is little in the way of medical teaching, but this

Digitized by Google

implies perhaps a greater degree of intellectual development than the venture can at present be said to possess. Doubtless it will come with the stage of ossification of epiphyses, for we are promised rules for guidance in "disease" as well as health.

Another paper to which we desire to draw attention is a modified form of the other two. Its claim for existence is also popular medical teaching, and its proprietor and editor is "a physician," whose identity is, however, a tolerably open secret.

As regards the intrinsic literary qualities of these publications, it might be allowable to take up an attitude of unconcern. We cannot, however, ignore the evil influence which they are calculated to exercise over the wholly unrestricted circle of readers to which they appeal, and which they aim at instructing in the elements, and as much more as possible of the art, of self-healing. It is to be hoped that this scheme to provide advice and medicine, but not medical attendants, for the general public may not incense that large body of medical practitioners whose existence it threatens, and whose livelihood it endangers, to such an extent as to injure that great metropolitan charity whose interests we all have so much at heart by the withdrawal of their support, which has so much contributed to its present success. Nor can we forbear from addressing another appeal to those of our brethren who, from what motive we cannot say, are lending their countenance and freely exposing their fair fame and names in defence of a journalistic scheme alike so prejudicial to the public good and so discreditable to the medical profession. What more can we say than has been said to warn them of the unwisdom of their present proceedings? Out of a sincere conviction that the course they are now pursuing is for them and for all concerned as mischievous as it is professionally unseemly, we have plainly put before them our views in the foregoing remarks. We would again earnestly request them to give these their most careful consideration. Let them be advised, in the common interest of themselves, their profession, and the sick who rely upon their skill, to withdraw their countenance from an undertaking which, if persisted in, must bring discredit and dissatisfaction to all concerned in it. Otherwise it is obvious that the authorities from which they derive their qualifications to practise cannot much longer shut their eyes to a matter so seriously affecting the honour and dignity of the profession.

IN his Morton Lecture Sir JAMES PAGET dealt in his usual felicitous manner with a question which, although not new, is now more full of interest than ever—the nature of cancer. He stated the case for its infectiveness, its dependence upon some specific organism implanting itself in a suitable soil, not only with more confidence, but with more fulness of supporting evidence and eloquence, than had previously been given. He, however, with a true scientific instinct, only formulated his views as a working theory, and by no means contended that the theory must be accepted as demonstrated, or the only one explaining the facts already known to us. The analogy between cancer and some of the specific diseases has been often dwelt upon, and it was a favourite theme of the late CAMPBELL DE MORGAN. But in recent years so many diseases, some of which were not generally recognised as infective, have been proved to be associated with the presence and development of micro-organisms that it is most reasonable to search eagerly for some like cause for cancer. The fact that careful observers like BALLANCE and SHATTOCK have failed to discover any cancer bacillus or cancer microbe of any kind is of the same importance as other negative evidence, and in no way closes the discussion. Indeed, almost while writing the intelligence comes that a German observer believes he has succeeded in recognising a cancer organism. To this matter, however, we refer in another column. Sir JAMES PAGET always states his case so forcibly and so charmingly, that it is difficult to resist the temptation to at once yield to the apparently inevitable and adopt his conclusion. And in this case we doubt not that many of his hearers and readers even went beyond the lecturer, and made up their minds that, as a matter no longer admitting of doubt, cancer is a microbe disease. Among other points which apparently tell against this view is the complicated structure of malignant tumours. When we compare cancer with tubercle, or any other of the undoubtedly infective diseases, we cannot but be struck by the fact that, while in the latter the growth is of the very simplest kind—an irritative hyperplasia of indifferent cells,—in cancer, the cells may be of the simplest, though their arrangement is often most definite. Further, it is noteworthy that, while the structure of a primary cancer is usually, perhaps we might say invariably, largely influenced by that of the tissue in which it grows, the structure of the secondary deposits shows little, if any, of this peculiarity. No doubt these facts may be capable of an explanation in conformity with the theory of the infective nature of cancer. But they are at variance with what we know of other infective diseases. Then, too, the question comes, Are we to believe that every form of malignant tumour recognised by the histologist has its own special microbe? From Sir JAMES PAGET'S allusion to the galls on the oak leaf we imagine that is his view, and that a squamous epithelioma of the anus owns a different cause from that of the columnar epithelioma of the rectum. There is nothing inherently improbable in this. Whatever may be the ultimate answer to the question of the origin of cancer, the important part played in its causation by the condition of the tissue of the part will remain unaffected. Should a cancer-germ be demonstrated, its harmlessness, except in a suitable nidus very specially prepared for its growth, is undoubted; and the discovery will have but little influence on the views now held on the heredity of the disease and other similar points.

Our columns have recently contained many letters on the question of the contagiousness of cancer, and no doubt the view that it is contagious will gain somewhat from the stress now laid upon its probable infective nature. Were its contagiousness proved, that would carry with it the fact of its being an infective disease. But we must say that the evidence in favour of its being contagious is far short of proof. Many of the cases published are probably coincidences; some of them may be shown to be only the similar results of one common cause. It is certain that, if contagious at all, it is so only to a very slight extent, that

Digitized by Google

all attempts to inoculate it have failed, and that cases appearing to support the view of its contagiousness are quite rare. Stress has been laid upon the instances in which epithelioma of the penis has occurred in the husbands of women with cancer of the uterus; but when we remember the great frequency of carcinoma uteri, it would be strange indeed if among the husbands of so many women some cases of cancer of the penis did not occur. Undoubtedly the evidence in reference to its inoculability must be received with caution, because the most ardent supporters of its infective nature must admit that a suitable nidus is an indispensable condition for the growth of the tumour, and until our experimenters have determined wherein this suitability of the tissues lies, and have tried the results of inoculation upon such suitable tissues, the negative evidence at present forthcoming is by no means conclusive.

We cannot close this article without some reference to Mr. CLAY'S work with Chian turpentine. The interest excited in this treatment by that gentleman's earlier articles has to a very large extent subsided, and the hopes once entertained that at last the cure for cancer had been found have been surrendered as failure after failure with the drug was experienced and reported. But Mr. CLAY has persevered in its use. He recorded last year a case of a gentleman, whom two of the most experienced surgeons in London had pronounced to be the subject of advanced epithelioma of the tongue. Under the Chian turpentine treatment he was cured. And last month we published a further short paper, containing no less than four cases in which the diagnosis of cancer was made by other surgeons, in one case confirmed by microscopic examination of a growth removed. All of these cases were first improved and then cured by Mr. CLAY'S treatment. What can be said of such cases? Were they *all* instances of mistaken diagnosis? If so, they were examples of disease which must in many other instances be mistaken for true cancer, and which ends fatally unless submitted to Chian turpentine. We think that, in spite of the many cases in which the drug has been shown to fail, the extreme importance of the question warrants a careful re-examination of all the evidence Mr. CLAY can produce. Whether this should be done by a committee, as in the case of the Hydrophobia Commission, or by individual observers, or by the staff of the Middlesex Hospital, who have unequalled opportunities of testing the value of Chian turpentine or any other drug for cancer, we are not prepared to state. But surely the matter ought not to be allowed to remain any longer in its present unsettled and unsatisfactory condition.

THE greater part of the time at the disposal of the General Medical Council, during the session which has just terminated, has been devoted to the consideration of the conduct of certain members of the medical and dental professions. The offences with which they have been charged have not been of the same type; they have varied between a serious indiscretion and a misdemeanour. The Medical Council have but one punishment for all offences which are brought to their notice—the removal of the name of the accused from the Register. In all cases where a previous conviction has taken place in a court of law the question of removal admits of no discussion; it is the natural sequence of the conviction. But in a case in which a practitioner is charged with "infamous conduct in a professional respect," the nature of the offence requires the closest consideration. It may well be argued that conduct less open to censure than that which can be regarded as "infamous" deserves the only punishment which the Council are empowered to inflict; that the members of an honourable profession must maintain a higher standard than that which falls short of the description embodied in the Medical Act if they are to be deemed worthy to be enrolled among its members; or in other words, conduct which is not "infamous" may still merit the removal of a name from the Register.

The Council are, however, necessarily guided by the law, and hitherto they have shown no desire to punish offenders beyond its limits. The cases before them during the autumn session have comprised that of a medical man convicted of publishing a false, scandalous, and defamatory libel; another who had been proved in a court of law to have availed himself of his position as medical attendant to create disunion between husband and wife, and to commit adultery; a dentist who had been guilty of persistent advertising, contrary to his distinct and repeated undertaking; the writer of a book of an undesirable nature; and a practitioner who had acted as "cover" to an unqualified assistant. The last placed himself in the hands of the Council, and promised that he would not further offend. It is obvious that no justification can be found for a practice which leaves sick persons solely under the care of unskilled persons, and giving to the latter a fictitious position, which is calculated to mislead those who seek their aid. The Council have dealt leniently with the case, and have decided to accept the assurance that this practice would be discontinued. There cannot, we think, be two opinions that removal from the Register would be well merited by such action, and it may be anticipated that future delinquents will receive a more severe punishment at the hands of the Council. In the remaining cases the General Council had, we think, no alternative but to purge the Register of the names of the offenders. A strenuous appeal was made on behalf of the practitioner accused of publishing a book which was *contra bonos mores*, not only by his counsel, but also by those who sympathise with efforts to limit the growth of population. We need not discuss the larger question under which the defendant sought to shelter himself; the point which the General Council had to decide was whether the character of the work which he published was detrimental to public morality placed as it was within the reach of the youth of both sexes. This, indeed, was their verdict; and the Council had we hold, no option but to regard this conduct as "infamous in a professional respect."

The opinion of counsel has been adverse to the application made by the Society of Apothecaries to grant registrable diplomas in Public Health. The 21st clause of the Medical Act of 1886 enables such diplomas to be granted by any College or Faculty of Physicians or Surgeons, or University, in the United Kingdom, and it is, we presume, held that the Society of Apothecaries does not come within this category. The delay is probably but temporary; the Society will, doubtless, appeal to Parliament to remedy this disability, and there is no reason why they should meet with opposition.

Digitized by Google

The last act of the Council was to adopt the Report of the Committee on the Registration of Foreign Degrees in Medicine. Henceforth, therefore, all foreign degrees in medicine which the General Medical Council are satisfied have been obtained after proper examination will be registered in cases where the holder is already on the Register by virtue of English, Scotch, or Irish qualifications. The effect upon English degree-conferring bodies will probably not immediately be seen, but it is likely that a larger number of practitioners will eventually seek this means of acquiring titular distinction; whether this will be done at the expense of British universities requiring residence, or whether foreign graduates will be recruited from the ranks of metropolitan students who are unwilling to present themselves at the University of London, the future must determine.

Annotations.

"Ne quid nimis."

THE HOSPITAL SUNDAY FUND.

THE meeting of the members of the Council of the Hospital Sunday Fund held at the Mansion House on Monday to receive the report of the Council promises well for the coming year of the Fund. This report, together with the discussion thereon, are printed in full on page 1138. The new Lord Mayor, the Right Hon. P. de Keyser, for the first time took his place in the chair, and was supported by the Lord Bishop of London, Sir Sydney Waterlow, and a very large meeting of the Council. The Lord Mayor gave very hearty expression to his sympathy with the Council, and his desire to imitate his predecessors in doing all that he could to uphold and increase its prosperity. The Bishop of London proposed that Sunday, the 10th of June, should be set apart for the great collection of the year. Besides, the meeting was large and representative of all creeds and classes. In the last fifteen years this Council has been the means of raising well on to half a million of money for the hospitals of London, or an average of £31,572 a year. It is satisfactory to find that the last years have been the best years, and that more was raised in the present year, in spite of the many calls of the Jubilee, than on any previous occasion. In the first four years of the Fund—on the whole, prosperous years—£111,075, were raised; in the last four—years of great depression—£154,656 have been raised—a difference of nearly £40,000. Four per cent. of the sum realised is set apart to purchase surgical appliances in accordance with Law 12. This is a great boon to the lame and the halt and the blind. These appliances include 299 trusses, 238 elastic stockings, 176 pairs of spectacles, 123 surgical boots, 162 spinal supports, 92 surgical boots with irons, 61 leg irons, 45 Martin's bandages, 21 poroplastic jackets, 37 artificial eyes, 37 artificial arms, 24 walking instruments, &c. The Fund is singular in its inexpensiveness, the working expenses only amounting to 4·200 per cent. of the gross receipts. There is still room for ingenuity in devising methods and arguments for the increase of the Fund. There is some reason to hope that the time of starvation of hospitals is coming to a close, and to the generous we would say that no channel more diffusive and discriminating could be chosen for their gifts than the Hospital Sunday Fund.

UNIVERSITY OF ST. ANDREWS: ELECTION OF ASSESSOR.

A KEEN contest is being waged for the above office as between the Right Hon. Viscount Cross, G.C.B., and Dr. John Duncan, M.A., LL.D., Senior Surgeon and Lecturer on Clinical Surgery to the Royal Infirmary of Edinburgh. Viscount Cross represents the interests of the Divinity and Arts Faculties of the University, and Dr. John Duncan the interests of the Science and Medical Faculties. In a general council like that of St. Andrews, where the science and medical graduates so largely preponderate, the result should not be doubtful, the more especially when, as in the present instance, several of the divinity and arts professors favour a scheme by which science and medicine would be virtually transferred to Dundee, and St. Andrews deprived in a good measure of its science and medical chairs, than which nothing could possibly be more disastrous. As is well known, the other Scottish Universities have greatly prospered because of the fostering and developing of their medical and science schools. The medical and science graduates of the St. Andrews General Council have now an opportunity of giving medicine and science in the old University a very substantial lift, and no doubt many will be glad to avail themselves of that opportunity. In politics both candidates are Conservatives, but politics in such appointments are very distinctly contra-indicated. It is well known that the fact of the appearance of Sir R. Cross in the field four years ago was due, not to any wish on the part of his proposer to benefit the University, but simply to capture the votes of a section and throw out Dr. Richardson. The two candidates, Dr. B. W. Richardson and Dr. Cleghorn, had been duly proposed and seconded, and the affair was supposed to be over, when suddenly one of the opponents of Dr. Richardson brought forward Sir R. Cross, for the avowed purpose of affecting the result by the introduction of a political element.

RANK OF ARMY MEDICAL OFFICERS.

WHEN the subject of the abolition of the term "relative rank" was being hotly discussed, we expressed our opinion that the Secretary of State for War might without difficulty devise some measure by which the relative status of the medical officers would be clearly defined and placed beyond the reach of cavil on the part of the few military officers who professed to believe that their military rank had been taken from them by the Royal Warrant of the 1st of January. Mr. Stanhope from the very first declared that the Warrant involved no such change, and that the rights and privileges of the medical officers remained untouched. With a view to put the matter beyond question, he has now intimated to the Royal College of Surgeons of Ireland that "in future, whenever a medical officer's name appears in the *London Gazette*, on appointment or promotion in the department, his corresponding military rank shall be announced, together with his departmental rank." It appears to us that this will place the matter beyond doubt, and that Mr. Stanhope has fully redeemed his pledge that no injury should result to the medical officers from the change in the wording of the Warrant. Of course this mode of dealing with the subject will not give satisfaction to those who, despising their professional status, are anxious to hide it under a title of *honorary* military rank, which they would share with the departments having no such claim as they have to consideration on the grounds of professional attainments and of the risks they incur in common with combatant officers. Such a change would, in our opinion, tend to lower the position of the medical officers. Under the existing system they have secured to them all the substantial advantages enjoyed by officers of the corresponding military ranks, without the assumption of titles which

Digitized by Google

could hardly fail to give rise to the impression that, instead of being members of a learned profession and scientific corps, they were merely combatant officers.

TOTAL BLINDNESS FROM CORTICAL LESION.

THE experimental researches of Munk and others have demonstrated that the centre for visual perceptions exists in the occipital lobes, and many clinical observations tend to corroborate this conclusion. Nevertheless, much yet requires to be accomplished, both experimentally and clinically, before this region of the brain can be completely mapped out into its functional areas. An interesting observation by Bouveret is published in the current number of the *Lyons Médical* (No. 46). The patient was a man aged seventy-two, who was found holding on to the trunk of a tree, having clearly been overtaken by a cerebral accident. He was able to walk, but with difficulty; his speech was not natural, and he could not give his address. On physical examination by Bouveret one day later, the patient was found not to be febrile; the intelligence was impaired to some degree, but there was no word-deafness. The pupils were moderately dilated, and acted but slightly to light. The man appeared to be totally blind. There was no motor aphasia; memory, however, is said to have been greatly deranged. The motility and sensation appeared to be unaffected; the cranial nerves were healthy; the optic discs were healthy. The urine contained a trace of albumen. There were no signs of valvular heart disease. The man lived for seventeen days after the onset of the brain disease; five days before death slight left hemiplegia, with contracture, appeared, the left arm and leg being affected, but the face not perceptibly. The necropsy demonstrated the existence of atheroma of the cerebral arteries; both posterior cerebral arteries were atheromatous and occluded by grey-red clots of firm consistence, and adherent to the walls of the vessels. In connexion with these arterial obliterations were found two areas of softening, of unequal extent, on the lower and internal aspect of the brain in the occipital region. The softening destroyed the cortical substance on the internal aspect of both occipital lobes. The cuneus was involved on both sides, and a large extent of the under surface of the temporal lobe in front of the calcarine fissure, but more on the right side than the left. The kidneys were the seat of an interstitial change. The left ventricle was very hypertrophied, and two thrombi undergoing softening were found in the heart; and from these, it is thought, emboli were derived which set up the thrombosis in the posterior cerebral arteries.

SMALL-POX AT LEICESTER.

DURING the past few days five cases of small-pox have been discovered at Leicester, all in the same family, the ages of the sufferers ranging from four to eighteen years. The first case was a boy aged seventeen, who on or about the 7th ult. had a very slight eruption, which was thought at the time to be chicken-pox. About twelve days ago—that is, early last week—three others of the family had a similar eruption. All these four had been well vaccinated, and the attack in each case was an abortive one, hence it was not until the youngest child, aged four years, sickened and an unmistakable rash of small-pox showed itself that the true nature of the disease was suspected by the medical attendant. This last patient is unvaccinated, and the attack is a severe confluent one. The origin of the infection has not yet been discovered, no small-pox having existed in the town for some two years. Suspicion points to the father of the present sufferers having brought it from Warwickshire, he being at work there and coming home to his family on Saturdays, but there is as yet no certainty about this, and further inquiries are being made. All the patients were in the hospital within a very short time of the cases coming under the notice of the borough medical officer of health, together with five others of the family who have not yet shown symptoms. These latter are being kept in quarantine. The house where the outbreak occurred and its contents have been thoroughly and efficiently disinfected, and the bedding &c. destroyed.

THE DEATH-RATE IN IRELAND.

THE last published Annual Report of the Registrar-General for Ireland showed that the death-rate in that portion of the United Kingdom in 1886 was 17·9 per 1000 of the estimated population, and was 0·4 below the mean rate in the preceding ten years, 1876-85. The recorded death-rate in England and Wales during last year was 19·3, and 0·8 below the preceding ten years' average. It would appear, therefore, that the Irish death-rate was 1·4 per 1000 below the death-rate in England and Wales; or in other words, it might be said that, in equal numbers living, 108 deaths occurred in England and Wales to each 100 in Ireland. Before accepting these figures, however, as correctly representing the relative mortality of these two portions of the United Kingdom, it is necessary to inquire whether there are any differences in the age-distribution of the populations, which might cause, at any rate a part of, this divergence between the two death-rates. Bearing in mind the marked proportion of emigration from Ireland that has taken place in recent years, consisting mainly of young adults, we should be prepared to find some wide differences in the age distribution of the remaining population, compared with that of the English population, which has not been subjected to so heavy an emigration rate. The Irish annual report, unfortunately, affords no assistance in determining the effect of its age-distribution upon the death-rate of the country, and does not even give a table of death-rates at different ages, which should find a place in every annual report, either local or national, upon health condition and mortality statistics, as the disturbance caused by variations in proportional age-distribution is thus, in great measure, eliminated. If we calculate from the census reports for England and Ireland, and compare the proportions of the population of those countries living at twelve different groups of ages, we find in the Irish population a considerable deficiency of children under ten years, and of adults aged between twenty-five and forty-five years, whereas at all other ages the proportions exceeded those that prevail in England. Perhaps the most noteworthy feature in the differences of age-distribution in the population of the two countries is the marked excess of elderly persons in Ireland. In each 1000 of the Irish population in 1881 there were 133 persons aged upwards of fifty-five years, against but 105 in England and Wales. If we carefully test the effect of this difference of age-distribution upon the death-rate, we find that the unfavourable effect upon the Irish death-rate of this excessive proportion of elderly persons is only partially counteracted by the small proportion of children under five years, and that the Irish death-rate in 1886 was 1·35 per 1000 in excess of what it would have been if the age-distribution of the population had been the same as it is in England. Stated in another way, if the age-distribution of the population in Ireland last year had been the same as it was in England, the Irish death-rate would have been but 16·5 per 1000 instead of 17·9. Therefore, after due correction for the effect of the different age-distribution of the population in England and in Ireland, it appears that the mortality during 1886, in equal numbers living, was as 117 in England to 100 in Ireland, instead of as 108 to 100, which was the proportion shown above without this correction for differences of age-distri-

Digitized by Google

bution. It may be assumed, therefore, that mortality in England exceeds that in Ireland by 17 per cent., and it becomes necessary to inquire what is the probable cause of this low death-rate in Ireland. It was for many years accepted as a fact, upon the authority of the Registrar-General's office, that a not inconsiderable proportion of deaths in Ireland escaped registration. As the Registration Act for Ireland was amended a few years ago with a view to secure more complete registration of births, deaths, and marriages, it is possible that civil registration in recent years has been much less defective than it was before the passing of the Amendment Act, and it would be interesting to know whether this is the view of the Registrar-General of Ireland. The low death-rate in Ireland, however, may probably be attributed mainly to the generally rural character of the Irish population. At the time of the last census in Ireland there were but three cities (Dublin, Belfast, and Cork) with a population exceeding 50,000 inhabitants, and but five other towns with populations exceeding 20,000 persons. When, therefore, the small proportion of urban population of Ireland receives due consideration, it would appear that the death-rate of that country should rather be compared with the rate in the rural districts of England, which in 1886 was 18·1 per 1000, and did not materially differ from the recorded rate last year in the whole of Ireland—namely, 17·9. It is evident that the recorded death-rates in England and Ireland, unless corrected for difference of age-distribution, are not fairly comparable.

TREATMENT OF THORACIC ANEURYSM BY THE INTRODUCTION OF WIRE.

M. CHARMEIL of Lyons (*Revue de Médecine*, Aug. and Nov. 1887) has collected the details of fifteen cases of aortic aneurysm in which "Moore's method," as he terms it, was employed, from the original case in the Middlesex Hospital to three previously unpublished cases in the practice of M. Lépine. Although not one of the fifteen cases has resulted in the cure of the aneurysm, M. Charmeil concludes that the practice itself does not involve any direct danger to the patient, and that the results ascertained at the necropsies have been encouraging. Clinically the treatment has nearly always been followed by local improvement, as well as by relief of subjective symptoms. He therefore thinks the method is justifiable and worthy of continued trial, and indicates as essential to its favourable practice a preliminary exploration of the aneurysm by means of acupuncture needles the use of the watch-spring of Bacelli introduced through a flattened cannula, and the most rigid adoption of antiseptic precautions. At the same time recourse should be had to Tufnell's dietetic treatment.

SCARLET FEVER AND MEASLES AT CLEATOR MOOR.

WE have for some time past noticed with regret the failure of the Cleator Moor Local Board to act according to the advice of Dr. Eaton, their medical officer of health, as to the closing of the schools, with a view to preventing a spread of scarlet fever and measles. The decision was arrived at very deliberately by a majority of five votes, three of which were given by members who were also school managers, and the schools remained open. We now find that up to Nov. 16th of this year there have been fifty deaths from zymotic diseases, as opposed to six during 1886, and that 743 cases of zymotic sickness have occurred, the attacks being mainly amongst young children. It is all but impossible to conceive of circumstances which could have led to worse results; and as the diseases went on extending, we can all understand the attitude of remonstrance which Dr. Eaton felt himself constrained to adopt. Now the sanitary authority have again refused to close the schools for a sufficient time to secure their proper cleansing and disinfection; and, in view of this, Dr. Eaton has informed them that it is obviously useless for him to attempt to influence them further in their doings, and that the responsibility must altogether lie with them. Dr. Eaton has all along done his duty, and he has now acted in a dignified manner. Article 94 of the Education Code of March 6th, 1882, distinctly implies that school closure shall be a matter to be dealt with under "medical authority," but by Article 97 it leaves the burden of responsibility with the sanitary authority, and the Cleator Moor Local Board must bear it.

POISONING BY CHARCOAL FUMES.

AN inquest was held recently at Petton, near Haschurch, on the body of George John Fry, aged ten. The deceased and his sister were put to bed in a room which contained no fireplace. As the apartment had been recently papered, the mother sought to counteract any possible effects of damp by placing in the room a bucket of burning wood ashes. On the following morning the deceased was found lying under the bed quite dead, his pupils being dilated; his little sister lay unconscious, with her face close to the bottom of the door. To this particular position she undoubtedly owes her life. Both children had vomited. The report of the evidence taken at the inquest states that the medical man who was called in attributed death to poisoning by carbonic acid gas. There seems little doubt, however, that the lethal effects were mainly due to carbon monoxide, although probably other oxidation products, to some degree, were factors in causing dissolution. The coroner and jury expressed their sympathy with the bereaved parents, who had acted kindly but unwisely. It is curious that past experience of such catastrophes as the above has not warned people of the danger that lurks in a charcoal stove. If the members of our School Boards require proof of the desirability of carrying out technical education, they may find it in the painful narrative now related.

CHILDREN'S WINTER DRESS.

THERE is a tolerably general impression in many quarters that in order to promote the health of children it is advisable to subject them to a "hardening" process. The meaning of this term it is needless to explain further than to say that its aim is to encourage native energy by opposition, to engender strength of mind and body by early participation in the struggle for existence. The principle is in itself a wholesome one, and is not without its parallel in the history of nature's processes. Care is most necessary, however, in its application. Without such care it may be, and frequently has been, overdone. In particular must it be remembered that all success in the adoption of this plan in education depends on the possession by a child thus trained of a basis of sturdy physical vigour. A delicate child, if treated after the same method, would languish and probably succumb. We have been led into this train of observation by noting the frequency with which one finds children of both sexes and of different ages, constitutions, and positions in life treated after one uniform prescription of hardy training. We would now concern ourselves particularly with that aspect of the question which has to do with clothing during such inclement weather as prevails at present. That considerable variation of opinion should obtain among parents with regard to this subject is only to be expected. Here, it may be said with truth, is room for the wise exercise of private judgment, and here we may in many cases find occasion to apply the maxims of the hardening system. So much may safely be granted, but we must not forget that certain essentials cannot be dis-

Digitized by Google

pensed with under any plan adopted. Among these the maintenance of bodily heat and dryness is all-important, and certain of the most prevalent customs of domestic life incline us to believe that the fact is but slightly understood. The hat, for example, is often, in the case of girls, far too light and too cool. Instead of straw, we would substitute some form of woollen material, just as boys, with few exceptions, are commonly provided with hats of wool or felt, which are at once light, comfortable, and suitably protective against weather. Under-clothing is another matter which does not as yet receive adequate attention. We still find the linen shirt or chemise worn very commonly next the skin. This is an error in personal hygiene which cannot under any system be excused. Summer and winter, indeed, present no material difference as regards the choice of an under-garment. Lighter or heavier, the material certainly should vary in accordance with the degree of external cold; but throughout the year no other substance is so wholesome or so preventive of chill as a woollen fabric. Of the feet we need, perhaps, hardly speak. For them, as for the rest of the body, a casing of wool is the prime requisite; and, indeed, the use of this material as a general investment for the skin will be allowed by members of the profession generally to be the great regulating principle in arranging the dress of children, whatever the view most approved in their physical education.

SANITARY CONDITION OF MARGATE.

WE learn with much satisfaction that the Town Council at Margate have at last awakened to the necessity of protecting the lives and health of the residents and visitors to this town. At a meeting, which was held on Tuesday, it was resolved that a drainage scheme for the whole borough should be provided without delay, and a committee was appointed to learn the systems in use in other places with a view to the adoption of that which is most suitable for the requirements of Margate. The Town Council have undoubtedly done wisely in deciding to remove from Margate the opprobrium from which the town now suffers. If they honestly carry out their intentions, it will not be long before Margate attains the high reputation to which it is entitled by its situation.

SMALL-POX IN RIO DE JANEIRO.

IT appears from the Monthly Bulletin on the mortality in the city of Rio de Janeiro, issued by Dr. J. Pires Farinha, that a remarkable epidemic of small-pox was recently prevailing there. These monthly returns show that in the first eight months of this year 2003 deaths from this disease were recorded within the city. The deaths both in January and in February numbered 74; in the following months they rapidly and steadily increased to 699 in August, the return for which month is the last that has yet come to hand. The population of the city is estimated at 400,000 persons, and the above-mentioned 2003 deaths from small-pox in the first eight months of this year were therefore equal to an annual rate of 7·5 per 1000 persons living. It may be noted that this death-rate from small-pox is more than three times as great as that which prevailed in London during the severe epidemic in 1871. The return shows that of these 2003 deaths from small-pox 1178 were of males and 825 of females; this inequality in the deaths of males and of females would probably be explained by the difference between the numbers living of each sex, as it appears from the census taken in 1872 that the population of the city at that time included 134,653 males and only 94,090 females. This marked inequality in the numbers of the two sexes would appear to occur principally between the ages of fifteen and thirty-five years, for of 715 deaths from small-pox occurring at these ages 517 were of males and only 198 of females. The small proportion of small-pox deaths occurring among children under five years of age, compared with those of adults, points to some exceptional features in this small-pox epidemic in Rio de Janeiro, of which Dr. Farinha's Monthly Bulletin does not afford the necessary explanation.

CONGRESS ON TUBERCULOSIS.

As we announced last week, an interesting gathering will take place in Paris from July 25th to 31st, 1888—viz., a Congress of Medical Men and Veterinarians to promote the scientific study of Tuberculosis in Man and Animals. The organising committee includes M. Chauveau as president, M. Villemin as vice-president MM. Butel, Leblanc, Nocart, Rossignol, Cornil, Grancher, Lannelongue, and Verneuil as members of the committee, and M. Petit general secretary. Certain questions have been prepared by the committee, but members of the Congress can also communicate papers on the subject apart from these. One day will be given up to anatomical demonstrations in M. Cornil's laboratory, another to examinations and necropsies on tuberculous animals at the Alfort College. The subscription for membership is 10 francs, and entitles the member to a copy of the Transactions of the Congress. The sittings will be public, all communications and discussions being in the French language. The questions proposed by the committee are: 1. On the dangers arising from the use of meat and milk of tuberculous animals; and preventive measures. 2. The races of man, species of animals, and organic media with respect to their liability to tuberculosis. 3. On the paths of introduction and propagation of the tubercular virus in the economy; and prophylaxis. 4. On the early diagnosis of tuberculosis in man and animals. Communications are specially invited on the subjects of heredity; contagiousness; experimental tuberculosis; variations in animals; the means of diagnosis between the lesions caused by Koch's bacillus and those due to other microbes, parasites, or foreign bodies; tubercular affections complicated with lesions produced by other microbes; mode of formation of giant cells; evolution of local tuberculosis; agents destructive of Koch's bacillus; the local and general methods which may arrest the extension of experimental tuberculosis; and the value of surgical treatment in the tubercular affections. Further particulars may be obtained of the General Secretary, Dr. Petit, 11, Rue Monge.

TOUTING PRACTITIONERS.

WE are flooded with handbills, cards, &c., announcing the cheap terms or the prodigious skill of their authors for the cure of all varieties of disease. In one case, advice and medicine are to be had for one shilling, children sixpence; in another, it is announced that a children's medical club will be opened in a grocer's shop, and that members, for one penny per week, will be entitled to free medical attention &c.; in a third, a simple card in a newspaper is made to do duty, inserted for weeks in succession in the leading papers of a large provincial town; in a fourth, a medical man—we will presume a very young one—advertises his address and terms on a card which is obviously meant for free distribution. For the present we treat these devices without reference to names; but we may not always be so considerate. If gentlemen of a liberal profession think it fair to violate all its traditional manners and methods, they must not be surprised if they are advertised a little more widely than they intended themselves to be. One of these gentlemen magnifies himself greatly. His experience, he tells his patient readers, is "as extensive as any physician in the West-end; such a man's fees for each piece of advice given is from one to three guineas, whereas Dr. [illegible]

Digitized by Google

charges no fee at all if treated at the surgery, *but just enough to pay for the best drugs"!* The benevolence of such practitioners excites more astonishment even than their skill. But, seriously speaking, touting practitioners are becoming a nuisance and a discredit, and will have to be dealt with either by the licensing bodies to which they owe their diploma or by their medical brethren.

THE BACILLUS OF WHOOPING-COUGH.

DR. AFANASIEFF has succeeded in finding and cultivating what he believes to be the true bacillus of whooping-cough. This microbe differs distinctly from all other bacteria which have been described. It is somewhat like Friedländer's pneumonia bacillus, but is shorter and thinner than the latter; besides, in gelatine it does not form nail-shaped cultures, those which are produced having no hemispherical head. Its potato cultures, too, are quite different from those obtained from Friedländer's bacillus. Afanasieff's bacillus exhibits a remarkable degree of vitality, for jelly cultures that have become dry and have been kept for four months, appearing under the microscope to be more or less destroyed, are still capable of producing fresh cultures when fresh media are inoculated from the dried mass. Dr. Afanasieff's researches were chiefly made from the sputum of some of his own children, who were affected with whooping-cough. The mouth was well washed out with a permanganate solution, and the mucus coughed up after the next paroxysm or two examined. In this mucus, after staining with methyl-violet, and in the pus-corpuscles contained in it, the bacilli could be seen with a magnifying power of from 700 to 1000 (Zeiss's eye-piece 3 or 4, $\frac{1}{17}$ oil immersion objective) as short rods, sometimes single, sometimes in twos, or even in short chains running in the direction of the mucus, sometimes again in small clusters. Their length was from 0·6 μ to 2·2 μ. Of course other bacteria were found. Pure cultures, however, were easily made on agar-agar, meat-peptone jelly, potato, &c. Dogs and rabbits were inoculated with a fluid culture mixed with chloride of sodium solution, some by means of injections into the trachea, others by direct injections into the lungs. All the animals were seriously affected, and many of them died. The symptoms were somewhat similar to those of whooping-cough, including cough, dyspnœa, and redness of the eyes. Many of the cases were complicated by broncho-pneumonia. On examining the bodies of those animals which died, the mucous membrane of the air passages was found much reddened, and coated with a tenacious clear mucus, in which, as well as in the pneumonic patches in the lungs, the bacilli were found. Similar appearances and the same bacilli were observed in the bodies of children who had died from whooping-cough. As to treatment, inhalations and spray of various antiseptic drugs would appear to afford the most ground for hope in relieving and shortening this complaint. The author points out that the quinine, benzoin, and other substances which have been used as applications to the nasal mucous membrane by Michael and others, under the idea of combating a reflex affection, are really, perhaps, beneficial from their property of destroying bacilli.

CHOLERA INTELLIGENCE.

No official intelligence is now published as to cholera in Southern Europe. From New York we learn that the passengers of the steamer *Britannia*, from Naples, who had been in quarantine since Oct. 18th owing to an outbreak of cholera on board, were permitted to land on Nov. 26th. There is also intelligence to the effect that, owing to the outbreak of cholera in Chili, communication between that country and the neighbouring States will be closed during the present month.

MEDICAL GRIEVANCES IN BELFAST.

THE *Northern Whig* of Belfast, of Nov. 21st, contains a very able address to the Medical Defence Association by Dr. Lindsay, the president. This address suffices to show that in medical matters, as in others, Belfast knows its own mind, and is very likely to realise its just claims to consideration. Dr. Lindsay deals chiefly with the grievances of Belfast under the new reign and *régime* of the Royal University. One chief complaint is that sudden and great alterations of the medical curriculum are sprung upon students in the middle of their course of study, contrary to the implied contract between Universities and their *alumni* that great changes shall not operate retrospectively. According to Dr. Lindsay, there are something like four pages of alterations in the recent Calendar of the University, affecting students who began their studies on different conditions. Another alleged grievance is the imperfect representation of Belfast in the Examining Board of the Royal University. At the recent examinations 60 per cent. of the successful candidates for the degree of M.B. were from Belfast, and yet there is only one Belfast examiner in thirteen. No wonder that Dr. Lindsay should complain. And the measured and dignified language in which he does so gives irresistible cogency to his case, and even to that part of it which claims a University for Belfast. He deals with the argument that there is not sufficient clinical material in Belfast for a great medical school, by arguing that such material exists in much larger degree than in Edinburgh, the largest British medical school. He regrets that, so far, difficulties have proved insurmountable in the way of bringing the union hospitals into use as a field for clinical study. But he still hopes for success, and points out that other great fields have been opened in the Belfast District Lunatic Asylum, the Ulster Eye, Ear, and Throat Hospital, &c. Other speakers criticised the curriculum of the Royal University. Not the least satisfactory part of Dr. Lindsay's address was his vindication of the character of medical students.

POISONING WITH COCAINE.

SINCE the first employment of cocaine as a local anæsthetic, frequent notes have directed attention to serious symptoms which appear to have been attributable to it These symptoms agree, in the main, in most of the recorded cases. Ordinarily the individual becomes deadly pale, and is found to be almost pulseless; occasionally throbbing in the head is mentioned; more usually there is faintness or giddiness, which may pass on to complete loss of consciousness, followed by severe prostration or continued giddiness. Severe vomiting and abdominal cramp are said to have resulted from taking nearly five grains of hydrochlorate of cocaine. In spite of this record, however, some scepticism exists concerning its toxic influence. It has been suggested that most of the symptoms may be regarded as resulting from fright of an impending operation. The smallness of the dose which has ordinarily caused alarm lends some weight to this hypothesis, although it would not explain the occurrence of vomiting. The last recorded case comes to us in too fragmentary a condition to be of much service in determining the question. We learn from an evening contemporary that M. Laborde communicated to the Physiological Society of Paris the fact of one of his colleagues having "narrowly escaped death from a dose of cocaine taken for the purpose of having a tooth extracted." The dose taken is not mentioned, nor is the time stated that elapsed before the alarming symptoms commenced, but we are told that "he became deadly pale, completely lost consciousness for a while, suffered intensely for some time, and had the sensation of approaching death." Although undoubtedly interesting, the account leaves much to be desired. At best it

Digitized by Google

suggests the need for a certain amount of caution in the use of cocaine, and also for fresh investigations to determine the conditions under which such toxic results are to be feared. The value of cocaine as a local anæsthetic is too great to allow vague suggestions of danger to pass unchallenged and unexplained.

SCARLET FEVER AND MEASLES IN BOLTON.

THE town of Bolton is suffering from an extensive prevalence of scarlet fever and of measles. Of scarlet fever 227 cases have been notified, and of these 62 have been removed to the infectious hospital, the remainder being dealt with in their homes. There are also some 200 cases of measles scattered about the town. From one school nearly one-half of the scholars have been absent, but the managers hesitate to take the step of closing it. The real value of school closing as a preventive measure lies in its application at the right moment; and hence the Education Department do not leave it to the managers to decide, but require the school to be closed on the instruction of the sanitary authority, who, in such a matter, are naturally advised by the medical officer of health. And not only so, but, though the managers may appeal against the closure, they are obliged to carry the instruction into effect pending the decision on their appeal. Such diseases as scarlet fever and measles are to a large extent distributed by the aggregation together of children in schools; and whilst it is of importance from one point of view that education should not be needlessly interfered with, it is equally imperative that the health and lives of children should not be sacrificed to a mere desire to promote mental culture, and to procure the full grant allowed by the central department for a large average attendance. When half a school is already absent through ill-health, this latter consideration hardly comes into play; for whilst no allowance is made for absent children in deciding as to the amount of grant, total closure of the school on medical authority is kept in view.

DEATHS UNDER ETHER.

A RECENT fatality under ether calls for comment. The verdict returned was "Death from syncope while inhaling ether," and so rarely is death occasioned by heart failure during the administration of this agent that one is led to inquire how such a casualty could be brought about. The patient, a female aged forty-five, was the subject of malignant disease of the mamma, and was actually undergoing an operation at the hands of one of the staff of the Hospital for Cancer, Brompton, when the death occurred. Ether was given by means of Mr. Clover's inhaler, and no premonitary symptoms of danger occurred. The patient's pulse suddenly flagged, and her face became cyanosed. The most strenuous attempts at resuscitation failed in their object, although persevered in for some time. Death from syncope under ether sometimes occurs at the very outset of the administration, and is then due to the excessive strength of vapour employed. In the later stages of ether narcosis, death from syncope is nearly always brought about by the non-admission of air; the patient is, in fact, semi-asphyxiated, and the heart, enfeebled by disease, is unable to stand the additional strain thus imposed upon it. Clover's excellent rule to raise the face-piece from the patient's countenance at every sixth respiration cannot be too strongly insisted upon, as when it is put into practice the danger of ether syncope is reduced to a minimum. Much as deaths under anæsthetics are to be deplored, there remains the comforting reflection that when ether is administered with proper precautions, and by a competent person, *who does not allow his attentions to be diverted from his patient*, little danger exists, at least from cardiac failure. The presence of valvular lesions of the heart does not contra-indicate, but rather calls for the employment of ether; and so the existence of "disease of the heart" recorded in the case of which we treat goes to show that ether was rightly employed. Of course, *arterial* disease is another matter, and graver risks are incurred by the use of ether when such is known to be at all extensive.

GLASGOW CENTENARIANS.

THERE has just died in Glasgow an undoubted centenarian, Miss Jane Gibson, probably the oldest inhabitant of the city, and one of the few links which connected Glasgow society of last century with that of to-day. Miss Gibson was born on May 22nd, 1785, and died on Nov. 25th, 1887, aged 102 years and 187 days. She came of an old family, and had led an active and intellectual life, being a member of the brilliant literary circle which graced Edinburgh in the early part of this century. To the last she retained the cultured tastes she then acquired. Until within a few days of her death her faculties, with the exception of her hearing, remained unimpaired, and she managed her household and business affairs herself. The *Glasgow Herald* points out that Miss Gibson was one of four undoubted centenarians of our day. All four were of the upper class, all four were women, and the two oldest of them were spinsters. First in the race was Ann Wallace, one of the twenty-one children of John Wallace of Kelly; she was born on July 1st, 1770, and died unmarried on Feb. 25th, 1873, aged 102 years and 239 days. Next to her, and distanced by 52 days, came Miss Gibson, referred to above. Isabel Ewing, daughter of William Ewing, Bailie of Glasgow, came next; she was born on March 25th, 1755, and died on Sept. 28th, 1885, aged 100 years and 187 days. Finally came Jean Brown, daughter of Alexander Brown, Dean of Guild of Glasgow, who was born on Nov. 15th, 1774, and died on Nov. 27th, 1874, aged 100 years and 12 days.

THE PROPERTIES OF ACETANILIDE.

MM. DESTRÉE and SLOSSE, of Dr. Desmeth's clinic in Brussels, have recently addressed themselves to the solution of some questions concerning acetanilide or antifebrin which have hitherto been left unanswered, or regarding which only contradictory observations have been published. Though acetanilide was credited with a microbicide action by Krieger on the ground of its success when used with collodion as an antiseptic application in surgery, Miquel has published some observations in the *Annales de l'Observatoire de Montsouris*, showing that considerable quantities of acetanilide may be introduced into broth cultures without hindering the development of colonies. In order to test this alleged property of the drug, MM. Destrée and Slosse inoculated a number of tubes of alkaline and slightly acid gelatine with bacterium aeriginosum in the Hygienic Laboratory of the Brussels University. In six days' time, when the gelatine in some control tubes had become liquid, that in the tubes containing 1 or 2 per cent. of acetanilide was still quite solid and unchanged in colour, presenting only a slight cloudiness near the surface, in which portion the microbe was seen by the microscope. It therefore appeared that the acetanilide, though it had retarded the development of the bacterium to a very marked extent, had by no means destroyed it. Regarding the effect of acetanilide on the vaso-motor nerves, Anseroff, in a paper read before the Moscow Congress last winter, showed reasons for believing that it acted as a stimulant to the vaso-dilator nerves. MM. Destrée and Slosse, however, after injecting one thigh of a frog with the drug, cut off the two thighs of the animal, and noted that the blood flowed much more freely from the limb that had not been injected than from the one which had, thus

Digitized by Google

showing that the acetanilide had had a vaso-constrictor effect. The effect on the blood has been studied by various observers. Hinsberg and Kast, and also Weill, have shown that ordinary medicinal doses do not affect the blood, but five or six grammes given to a medium-sized dog produced cyanosis, due to the transformation of the hæmoglobin of the blood into methæmoglobin. Hinsberg and Kast, and also Murray, found that the blood pressure is augmented by acetanilide, and Reise speaks of the pulse as being increased in tension. Hare (*Detroit Therap. Gaz.*), on the other hand, found the reduction of temperature frequently accompanied by a diminution of the intra-arterial pressure, which, however, was interrupted by sudden and inexplicable augmentations. MM. Destrée and Slosse carried out a series of observations on rabbits with a Ludwig's kymograph in the Physiological Laboratory of the University of Brussels, and found that the pressure in the carotid could be lowered from forty-five to thirty-one millimetres by three injections of one centigramme of acetanilide. The reduction appeared, however, to be temporary only.

DESTRUCTION BY ARTIFICIALLY INDUCED DISEASE.

THE proposal attributed to M. Pasteur that colonists should call disease to their aid for the extermination of rabbits has properly shocked the sensibilities of the world. It has already been compared to the poisoning of wells in a hostile country, a mode of warfare which would be considered disgraceful to any civilised nation. The suggestion that artificially induced disease should be utilised for the killing of the lower animals could hardly have originated in the mind of a medical man. We hope this will be clearly understood, and that no mistake on this point will allow Medicine to be accused of a thought so foreign to her best teachings. If disease came to be regarded as a means of war against pests, it would perhaps not be long before the revolting proposal were entertained by hostile nations for the "removal" of their enemies. Civilisation places some restrictions upon the actions of individuals, and certainly a proper sentiment recoils from the proposal to thus misuse medical knowledge.

MERCER'S HOSPITAL, DUBLIN.

FOR a considerable time past, as the medical profession in Dublin are aware, there has been a great want of harmony among the medical staff of this institution. This at last culminated in a notice of motion by Dr. Knight to the effect that Mr. E. Stamer O'Grady (the senior surgeon) should be removed from the hospital by reason of his having acted against the duty of his office and the general interest of the corporation. Accordingly an inquiry of a most exhaustive nature was held by the governors, all parties being represented by counsel, and, at the termination of the evidence, which was most voluminous, the inquiry was adjourned to the 28th ult. (last Monday) in order to hear counsel on both sides. Owing, however, to the illness of the assessor it has been further adjourned to the 12th inst., when it seems extremely probable that some kind of compromise will be effected between the litigants. Certainly, so far as the interests of a charitable institution are concerned, it is of vital importance that the hospital staff should work in harmony for the future or new men be appointed in their place. It is unnecessary, even if we could spare the required space, to enter into the series of charges made against Mr. O'Grady by his colleagues; they, however, may be said to consist chiefly of a certain irritability of temper, harshness to the nurses and house-surgeon, and want of concord with the other members of the staff. We have read carefully all the evidence, and are compelled to come to the conclusion that the various allegations are indeed very petty, and certainly most inadequate to demand the resignation of an accomplished surgeon, such as Mr. O'Grady undeniably is. The trivial complaints and evidences of alleged bad temper and incompatibility have been dilated on *ad nauseam;* but it has never for a moment been put forward that Mr. O'Grady has ever failed in professional ability, or shown any languid interest in the prosperity of the hospital with which he is connected. This being so, it would, in our opinion, be contrary to the claims of justice, and would unquestionably furnish a bad precedent, if the governors—or rather a majority of those gentlemen—were to remove the defendant, and thus cause irreparable injury to his professional reputation. We sincerely trust, for the sake of an old institution, of the medical staff generally, and of the interests of the community at large, that an amicable understanding may be come to between Mr. O'Grady and his colleagues; and that for the future all parties may work harmoniously together, and by every means in their power combine to advance the reputation and well-being of Mercer's Hospital.

FEVER IN LONDON.

THE number of cases of scarlet fever admitted into the hospitals of the Metropolitan Asylums Board during the week ending Nov. 26th showed an increase upon the previous week, the numbers being respectively 191 and 174, thus showing that the epidemic followed the course indicated by the experience of previous years. Fresh cases are now again diminishing, and it may be expected that this decline will be steadily maintained until the termination of the epidemic. Enteric fever is, however, increasing, the patients admitted during last week being twenty-six, or twelve in excess of the preceding week. No case of small-pox or typhus fever was reported, the metropolis having remained free from the latter disease for some weeks.

HYDROCHLORIC ACID IN GASTRIC JUICE.

A SATISFACTORY reaction for hydrochloric acid in gastric juice appears still to be an unsupplied want. M. Ewald has brought forward a new reagent for the detection of free hydrochloric acid. It is composed of one part of vanillne, two parts of flucoglycine, and thirty of alcohol. On warming slowly the liquid to which the reagent is added, there appears a beautiful crimson-red colour if the liquid contains hydrochloric acid in not less proportion than ·05 gramme per litre. Lactic acid does not give this reaction.

PARTNERS ON A HOSPITAL STAFF.

THE question is sometimes asked whether it is for the good of a hospital or an infirmary that two or more members of a family or a firm should be on the honorary staff. It is evident that in some circumstances two partners may be so specially fitted for such an appointment, or so markedly superior in skill and experience to their competitors, that it would be an injury to the institution and an injustice to the patients to refuse to elect them. It is, however, equally evident that there are grave disadvantages in allowing the working of a hospital to fall in an undue measure into the hands of any one individual, and perhaps still more of any one family or firm of partners. One of the important objects for which hospitals are maintained is the aid they afford in the diffusion of medical knowledge. It is a good thing to have this benefit shared by as many practitioners as possible. Anything like a clique on a staff is thoroughly bad, and seriously interferes with the proper working of a hospital. It would be undesirable to make any rigid rule in such a matter as this, but we can hardly imagine any circumstances in which it

Digitized by Google

would be right to have more than two members of a family or firm holding office at the same time; and when the claims of rival candidates for a post are fairly balanced, the fact that one of them is connected with an acting member of the staff should, as a rule, be held of sufficient importance to turn the scale against him.

HEREDITY AND NURTURE.

MR. FRANCIS GALTON'S first lecture on Heredity and Nurture at the South Kensington Museum on Saturday last called together a large audience, composed in part of the ordinary students of the school, but also including several doctors and actuaries interested in the subject. The lecturer dealt mainly with methods of exact human measurement, using the word "measurement" in its widest sense. He exhibited improvements upon the instruments employed at the Health Exhibition in 1884, and showed an instructive series of curves indicating the strength of pull, the swiftness of blow of arm, the weight, the height, the breathing capacity, and the keenness of sight deduced from observations upon a very large number of individuals. In conclusion, he urged the need for a permanent anthropometric laboratory, with a library of family records and biographies, thinking that the library might ultimately become a most important store-house of materials for the study of hereditary faculty. Mr. Galton caused some amusement by a "curve" he had constructed from the data given by Sir James Paget in his well-known paper upon "What becomes of Medical Students."

MEDICAL HONOURS.

THE Queen has been graciously pleased to give orders for the appointment of the following, amongst other officers, to be Companions of the "Distinguished Service Order":—Surgeon-Major Thomas William Patterson, Medical Staff; Surgeon-Major Robert de la Cour Corbett, M.D., Medical Staff; Surgeon-Major Frederick William Wright, Indian Medical Service, Bengal; Surgeon Alfred William Frederick Street, Indian Medical Service, Bombay; Surgeon Alexander Peers Adams, Indian Medical Service, Madras; and Surgeon William Ainley Sykes, Indian Medical Service, Bengal. The Queen has also been pleased to direct that these distinctions shall take effect from July 1st, 1887.

AN INTERESTING PROBLEM.

CAN a man cough himself to pieces? At an inquest recently held on an inmate of the Borough Asylum, considerable interest was attached to the finding of a broken rib in the body of the patient. The doctor who gave evidence endeavoured to point out that under some abnormal conditions bones may be broken during life by muscular efforts, or even by the act of violent coughing. The coroner, in commenting upon this, appeared to have much difficulty in recognising the existence of such an unusual occurrence, and naïvely stated to the jury that they would doubtless have equal hesitation in appreciating the learned theory that it was possible for a man to cough himself to pieces! A perusal of the writings of Dr. Weir Mitchell and Prof. Charcot will show that spontaneous fracture of the bones in locomotor ataxy is not uncommon; the importance of this in medico-legal inquiries is worth remembering, and throws much light upon questions affecting the treatment of the insane.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. André J. Duval, of Geneva, author of a classical work on the History of Medicine.—Professor Fechner, of Leipsig.

THE CROWN PRINCE OF GERMANY.

SIR MORELL MACKENZIE continues to receive highly satisfactory reports as regards the present condition of the Crown Prince of Germany. The slight enlargement of the left submaxillary gland which took place at the end of October was followed by a similar swelling on the opposite side after the occurrence of œdema in the early part of November. Considerable diminution has taken place in both these swellings. Sir Morell Mackenzie considers that in view of the fact that there has been no actual microscopic proof of the existence of cancer, the diminution in the size of these swellings is not without a certain degree of clinical importance.

ALLEGED DISCOVERY OF A CANCER BACILLUS.

As might have been expected, the statement so widely circulated a week ago, to the effect that Dr. Scheuerlen of the Charité Hospital, Berlin, had discovered "the cancer bacillus," has received much qualification. It has since been declared that the inoculated animals have not exhibited any evidence of cancerous formation, and it is hinted that the experiments are very incomplete, and the "discovery" has been announced "more with regard to the present circumstances than to scientific accuracy." Should this be the case we may refer Dr. Scheuerlen to the inquiry conducted by Messrs. Shattock and Ballance, and communicated some months ago to the Pathological Society. He will find there a series of arguments in favour of the parasitic theory of cancer, but, on the other side, he will see that these investigators failed in obtaining any distinctive micro-organisms, by the cultivation process from either healthy or diseased tissues. They did occasionally get evidence of contamination with bacteria, and it would be well to know what precautions were taken by Dr. Scheuerlen to avoid such contamination. Messrs. Shattock and Ballance suggest that the parasite is not bacterial, but possibly allied to the lowest protozoa; and the want of confirmation of the discovery of the bacillus will harmonise with their negative results.

CHROMOGENIC MICRO-ORGANISMS.

IT has been found that ·03 per cent. of a gramme of corrosive sublimate prevents the colouration of artificial cultures of the pyocyanogenic microbe and of the fluorescent microbe of the rabbit's intestine, whilst it requires ·04 per cent. to arrest the growth of the bacillus. MM. Roger and Charrin, having determined this fact, point out its possible application in the antiseptic system, since it may be practicable to render the microbe harmless without destroying its life, and consequently perhaps without killing the vital tissues in which the germ may be growing.

MEASLES IN THE HEBRIDES.

THE effects of an epidemic of measles in a population living in insanitary conditions, and presenting to some extent a virgin ground for the poison, are well illustrated by the serious and fatal outbreak of the disease in the Hebrides, more especially in the small island of Eriskay. This island, which forms part of South Uist, lies in the sound between South Uist and Barra, and contains a population of about 480, living on sixty small crofts. As these crofts are too small to support so many, nearly all the able-bodied men and many of the young women go every summer to the fishing on the east coast of Scotland. At Fraserburgh, in July and August last, measles broke out among those engaged in this work, and three girls from Eriskay died. Others brought home the infection in September, and since then the increase has spread widely.

Digitized by Google

In Eriskay eight people have died in less than two months, two of these being strong men. The disease has entered almost every house. The infection was carried to Barra, where several deaths have occurred. In South Uist also over 100 persons are at present ill. Bad feeding, bad housing, and want of proper attendance seem to account for the unusual fatality of the epidemic.

PHARYNGEAL VEINS.

ON the posterior and lateral walls of the pharynx a network of veins exists, having very unequal meshes. The principal efferent vessels empty themselves into the internal jugular veins, and communicate superiorly with the pterygo-palatine vessels, median and posterior meningeal. The plexus is the terminal for numerous veins which proceed from the muscles, and especially of the mucous coat of the pharynx, beneath which they form the submucous network. MM. Bemiar and Lapeyre have studied specially this network, which is found to present at the level of the inferior part of the posterior wall of the pharynx a very remarkable deep plexus, not described by authors, and merely mentioned by Cruveilhier. It is constant, and met with at all ages. It exists between the mucous coat in front and the inferior constrictor muscle behind, whilst the inferior angle of the middle constrictor partially conceals it. Irregularly oval in shape, its larger extremity is superior; it is composed of an agglomeration of a large number of veins ranged one against another, frequently anastomosed; and into it run veins from the pharyngeal mucous membrane, which form fine arborisations around it.

THE TREATMENT OF HEADACHES BY NITRO-GLYCERINE.

DR. TRUSEVICH publishes in the *Ejenedélnaya Klinicheskaya Gazeta* a series of observations on the effect of nitro-glycerine on headaches. He adopts in the main the classification of headaches made by Dr. Day, whose work he translated into Russian, in which language it has already gone through two editions. The preparation generally used was the 1 per cent. alcoholic solution, though in a very obstinate case the 10 per cent. solution was used, two drops being first given, and after an interval of two minutes three more. The result of this heroic medication was that the patient, a girl of fifteen, became pallid, and her pulse very weak; however, a little water and some smelling salts quickly revived her, and she was none the worse. The nitro-glycerine had no effect on the headache, which was of a persistent character, and was probably due to some organic lesion, perhaps an affection of the cranial bones. As a rule, two or three one-drop or two-drop doses of the 1 per cent. solution placed on the tongue at intervals of a very few minutes sufficed to arrest the headache. The conclusion arrived at was that all cases which depend entirely, or almost entirely, on a vaso-constrictor neurosis are immediately curable by nitro-glycerine. In cases where the cerebral anæmia is partly due to deficiency or poorness of blood, milk, iron arsenic, quinine, and other tonic remedies are of course required in addition to the nitro-glycerine. The chief indications for the successful treatment of migraine by nitro-glycerine are pallor of the face and a paroxysmal character of the pains, also their augmentation on pressure of the carotids, and their diminution when the head is lowered. In "nervo-hyperæmic headaches" nitro-glycerine is useful, but it only acts indirectly by dilating the vessels in other parts of the system, and thus relieving the congestion in the cerebral vessels. It is positively injurious in headaches depending on passive hyperæmia. On this subject, however, Dr. Trusevich promises a future article. As a rule, he thinks that if nitro-glycerine fails to relieve, the prognosis is probably bad, as the pain is generally due to some organic lesion, such as thickening of the fibrous coverings following chronic alcoholism or syphilis, or to some osteophyte caused by periostitis, or, lastly, to morbid changes in the cranial bones. In some headaches of rheumatic origin nitro-glycerine appears to have some effect, but Dr. Trusevich thinks that in others massage would probably be more beneficial. Where headaches are due to heart, lung, or to hepatic disease which causes passive congestion in the cerebral vessels, nitro-glycerine cannot be expected to do much good.

EPIDEMIC INSURANCE MOVEMENT.

AN excellent system of insurance against the small-pox prevalent in Sheffield has been set on foot by workmen in more than one factory. It having come to their knowledge that some of their fellow-workmen continued their attendance at the factory, although they came from infected houses, they called a meeting, at which it was decided that pending the period of danger a levy should be made, amounting to 2½ per cent. of each man's average earnings, so as to provide a fund out of which any man coming from a house where there was small-pox could be paid his average weekly wages, until it was certified that there was no further risk of infection. The example is worthy of imitation for diseases other than small-pox.

ENDO-LARYNGEAL EXTIRPATION OF BENIGN GROWTHS.

IN the account published last week of Professor Schnitzler's paper on Malignant Degeneration of Laryngeal Papillomata, the accidental omission of a negative made it appear that Professor Schnitzler discountenances endo-laryngeal operations. This is on the face of it so contrary to practice, that few, we hope, have been misled by the statement. Indeed, Professor Schnitzler stated the exact opposite, for he intimated that the occurrence of such malignant degeneration, even if favoured by repeated attempts at removal, should by no means be held to condemn endo-laryngeal extirpation of benign growths. The rarity—sufficiently exemplified in the remarks made at the discussion—of malignant degeneration is of itself sufficient to prove that external irritation plays little, if any, part in the morbid change.

PHYSIOLOGY OF RENAL SECRETION.

SOME time ago Max Hermann stated that the secretion of the kidneys varied on each side. It was objected to his experiments that reflex influences consecutive to exposure of the ureters might explain the difference. Zuelzer has studied the question in a case of vesical ectopia. Iodide of potassium, given by the mouth, appeared in the urine from one ureter at a different time from that of the other side; salicylic acid showed the same difference. Chemical analysis also proved that the proportions of urea, phosphoric acid, and sulphuric acid differed on the two sides. Great differences were observed in the quantity and density of the urine discharged from the two sides respectively. This difference leads Zuelzer to think that the composition of the blood in the aorta is far from being uniform.

FOREIGN UNIVERSITY INTELLIGENCE.

Halle.—Dr. Friederich Kretsch has qualified as *privat-docent* in Otology.

Marburg.—Professor Roser will retire at the end of the winter session, when he will have been fifty years in practice.

Moscow.—A Clinic for Mental Diseases has just been opened under Professor Kojevnikoff. This is said to be the

Digitized by Google

first clinic of the kind opened in any Russian university, though something of the kind exists in connexion with the St. Petersburg Military Medical Academy.

Munich.—Dr. Tappeiner, Professor in the Veterinary School, has been appointed Extraordinary Professor of Pharmacology in the University.

Zurich.—Professor H. v. Meyer celebrates the fiftieth anniversary of his promotion to the degree of Doctor of Medicine on Dec. 2nd. The medical students have been preparing a grand festival *commers* for the occasion.

ILLNESS OF LORD LYONS.

FROM the bulletin published on the morning of the 1st inst. it appears that Lord Lyons, of whose illness our readers will be aware, passed a quiet night, and that his strength is fairly maintained. An account received at the time of our going to press states that no change has taken place in his lordship's condition.

THE large number of seventy-four students have enrolled their names for a course of lectures on Diseases of the Ear just begun by Dr. Thomas Barr at the Glasgow Ear Hospital. When it is considered that this is an optional course of study, and that in their professional examinations students are not tested as to their knowledge of this branch of study, such an attendance must be considered as most satisfactory, and is a good indication of the quality of students attending the Glasgow medical schools. The ordinary attendance on this course in the past has been from ten to twenty, so that the contrast this year is very striking.

A PETITION has been presented to Her Majesty in Council by the Royal College of Physicians of London and the Royal College of Surgeons of England praying for the grant of a Charter under the style of "The Senate of Physicians and Surgeons," with power to grant degrees in medicine and surgery. The petition will be considered by a committee of the Privy Council on Jan. 16th.

THE House Committee of the London Hospital have, at the request of their Imperial Highnesses the Crown Prince and Princess of Germany, granted permission to Mr. Mark Hovell, assistant aural surgeon of the hospital, to attend the Crown Prince during the remainder of his illness, without his incurring the loss of his appointment.

WE understand that Dr. Bruce Low, M.D. and C.M. Edin., medical officer of health for Helmsley, Yorks, and Treasurer of the Yorkshire Association of Health Officers, has been appointed by the President of the Local Government Board to a medical inspectorship of that Board.

ON the 24th ult. Dr. Watkins of Newton-le-Willows met with a serious accident whilst driving. The horse shied at some object, and the unfortunate gentleman was thrown out of his conveyance, falling on his head and sustaining concussion of the brain.

THE Bradshawe Lecture will be delivered at the Royal College of Surgeons on Wednesday next, Dec. 7th, at 4 P.M., by Sir Joseph Lister. The subject will be "On the present position of Antiseptic Treatment in Surgery."

ON the 19th ult. an inquest was held at Newcastle-under-Lyme, on the body of a man aged sixty, who died on the previous day from blood-poisoning caused by the scratch of a cat.

Pharmacology and Therapeutics.

SALOL, BETHOL, AND NAPHTHOL.

GOSPODIN VILENTS of Dorpat has published an account of some researches he has been making, with a view of determining the therapeutic value, from a veterinary point of view, of some new drugs. The salols, he finds, lower the temperature in healthy animals, but in large doses salol gives rise to toxic symptoms. This class of bodies, too, does not behave alike with different species of animals. Bethol, which is naphtholol-salicylic-ether-naphthol, $C_6H_4 . OH . COO . C_{10}H_7$, and which is prepared by the action of oxychloride of phosphorus on a mixture of β-naphthol and salicylate of soda at a high temperature, appears to have a beneficial action in intestinal affections. For injection into the bladder or uterus salol is preferable. Bethol does not appear to have much power of destroying parasites (entozoa) or bacteria. The author thinks that the salols will displace salicylic acid for internal use. The former bodies have, however, a peculiarly toxic action on cats, and they must evidently be prescribed in general with caution. Naphthol in its crude state always contains carbolic acid; pure β-naphthol dilates the vessels in frogs, and acts as a muscle rather than as a nerve poison. It increases the peristaltic action of the bowels when administered by the mouth or subcutaneously. It seems to have anti-helminthic and cathartic properties.

STROPHANTHUS.

Strophanthus having been as yet but little employed in Russia, Dr. A. Kazem-Bek writes to the *Vrach* strongly recommending its trial in cardiac cases, both on the ground of his clinical and physiological observations, and from the experience of foreigners of various nationalities. He gave it in several cases both of organic and functional disease occurring in private practice, and was much pleased with its results in all except one case. Its beneficial effects in the alleviation of dyspnœa, and of both bronchial and cardiac asthma, were very marked. The heart's contractions became much less frequent, the circulation of the blood improved, and the quantity of urine excreted was greatly augmented. In consequence of the amelioration in the general condition, and perhaps owing to a direct action of strophanthus on the brain, the patients obtained prolonged and quiet sleep. Indeed in some instances drowsiness overcame them shortly after they had taken a dose of the drug. In experiments on dogs, too, a similar soporific action was observed. From the physiological observations made by Dr. Kazem-Bek, he concludes that strophanthus is not a mere muscle poison, but that it exerts an influence on the terminal branches of the vagus in the cardiac ganglia, and on these ganglia themselves. Were it not so, he says, atropine administered subsequently to strophanthus would not produce acceleration of the cardiac beats, but strophanthus administered after atropine would diminish the frequency of the heart's contractions, but neither of these results ever obtained in his experiments. The increase in the blood pressure caused by strophanthus does not, he believes, depend on the cardiac contractions, since it rises, while the contractions continue perfectly unchanged.

ARSENIC IN CHLOROFORM.

Scholvien has detected traces of arsenic in many samples of chloroform. This may be accounted for by the presence of arsenic in the sulphuric acid or manganese used in the preparation of the chloride of lime with which the chloroform has been made. He suggests that in order to examine a suspected sample for arsenic the chloroform should be stirred with absolutely pure dilute potash, then evaporated and the residue tested by Marsh's process. When arsenical chloroform is distilled, Scholvien is positive that all the metal remains behind, none passing over with the distillate.

ICHTHYOL.

Ichthyol has now been in use some years, and bids fair to maintain its original reputation as a valuable medicament of very wide application. It is employed pure in rare cases, but more frequently in solution in water, oil, or glycerine of the strength of 20 to 50 per cent., for external applications

Digitized by Google

in bruises, sprains, rheumatism, burns, chilblains, &c. It may be administered internally in 1 per cent. solution, or in the form of pills, in cases of chronic skin disease, gastric affections, and rheumatism. As a spray in 10 per cent. solution it has been employed in the treatment of throat and nasal affections. Ointments of various strengths are compounded for external inunction in erysipelas and rheumatism. An alcoholic ethereal solution of the strength of 10 per cent. has been successful in relieving neuralgia when sprayed on the painful region; stronger solutions are used for sciatica and lumbago. Plasters and fomentations of ichthyol are also used, and a soap is made for preserving the skin and relieving chapped hands and kindred ailments.

PHTHALATE OF MORPHIA.

Herr Bombelon, writing in the *Pharmaceutische Zeitschrift*, strongly recommends the phthalate in preference to other salts of morphia for dispensing and hypodermic use. It is prepared in the form of small vitreous laminæ, and by a process similar to that by which other "scale preparations" are produced.

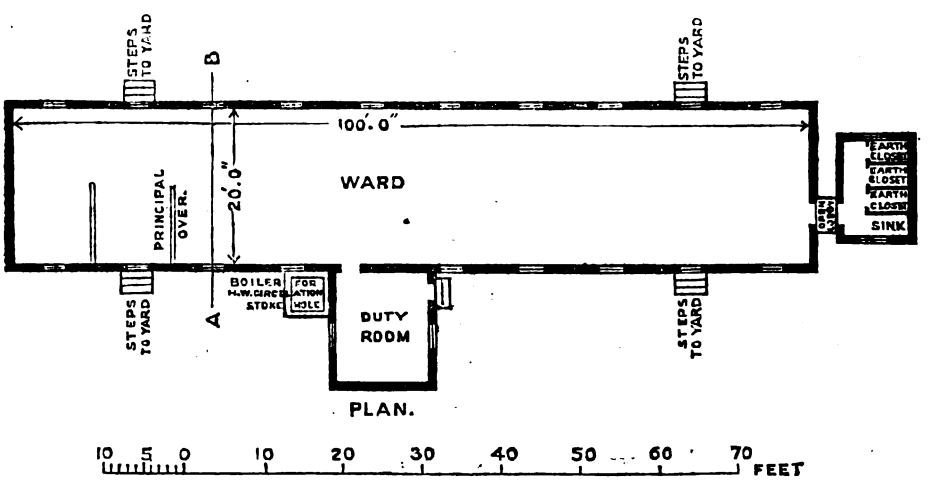
EMULSIONS.

The *Monthly Magazine of Pharmacy* quotes a suggestion of a German pharmacist as to making emulsions. First pour 7½ parts of water into a phial, then 10 parts of almond oil, and next 5 parts of the best gum arabic in very fine powder, and shake energetically. After a while add gradually water to make up 100 parts. The resulting emulsion will be faultless.

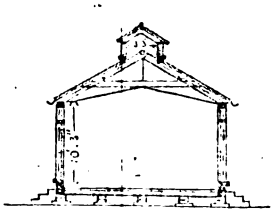
ACONITINE.

In a recent Dutch work by Dr. van Renterghem, it is stated that there exist no less than eight different kinds of aconitine in the various European markets, differing from one another to such an extent that some samples are several hundred times more poisonous than others.

OXALIC ACID IN SPIRIT OF NITROUS ETHER.



A German chemist has found that large quantities of oxalic acid exist in the residue of the still with which spirit of nitrous ether has been prepared. It is possible therefore that it may sometimes form an unlooked for impurity in this compound.



TEMPORARY HOSPITAL ACCOMMODATION.

THE demands upon the Metropolitan Asylums Board for increased hospital accommodation has led to the erection of temporary huts on the grounds of the different hospitals, of which those at Homerton are especially deserving of commendation. The huts at this institution are five in number, four being 90 ft. and one 100 ft. long, the width of each being 22 ft. They are constructed entirely of wood on small brick piers, and the floors are raised about a foot above the ground. The boarding both of the roof and walls is double, with an interspace of four inches, and the roof boarding is covered externally with tarred felt. All the woodwork is left plain; there is no painting, staining, or varnishing. The windows are French casements opening down to the ground, and above each window is a hopper fanlight, which can be opened at will. In addition to the window ventilation, there is a louvred ventilator, which is permanently open, running the whole length of the apex of the roof. The ventilation is therefore very ample, and in mild weather, when all the French windows are open, the patients may almost be said to be treated in the open air. The temperature of each hut is maintained by hot-water pipes connected with a small boiler outside. Leading out of the ward is a small kitchen, provided with a sink, a gas stove, and a gas-heated bath. The closets, which are earth commodes, are placed in a small annexe connected with the ward by a covered way, which is quite open at the sides. The huts are admirably adapted for hospital purposes, and the architect, Mr. Keith D. Young, has acted on Dr. Collie's suggestion as to the character of ventilation required for patients suffering from infectious diseases, and has kept the cost within very narrow limits, the total expenditure being about £20 for each thousand cubic feet, this amount, under the special circumstances of the ventilation, being found sufficient for one bed. As evidence of the rapidity with which the huts can be erected, it may be stated that they were occupied within less than a week of the order being given to Messrs. Lascelles, the builders. The accompanying sketches show the planning and arrangement of the different parts of the hut, as well as the dimensions.

HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held on Monday last at the Mansion House, under the presidency of the Lord Mayor.

Sir SYDNEY H. WATERLOW said he desired, before the regular business commenced, to propose a resolution expressing the deep regret of the Council at the loss they had sustained by the death of their esteemed colleague, Sir William McArthur, who had been a member of the Council ever since its establishment in 1873, and a member of the Distribution Committee for the same period. Those who looked at the list of distribution from year to year, and were aware that they were not made until after a most careful examination of the accounts of each hospital and dispensary, would understand something of the labours of the Distribution Committee, and of the greatness of the loss sustained in the death of Sir William McArthur.

The Rev. Canon FLEMING seconded the motion. He stated that he had been chaplain to Sir William McArthur during his year of office, and he had known and esteemed him long before. He had a deep knowledge of his character, and all who knew how good and genial and zealous he was, not only in regard to the Hospital Fund, but in every good work, would deeply deplore the loss which all the churches had sustained in his death.

The motion was unanimously adopted.

The LORD MAYOR desired to say a word or two before calling upon the secretary to read the report. He begged to assure the Council, in taking the chair for the first time as Lord Mayor, that it was his earnest desire to do everthing to promote the interests of the very important work they had in hand. He should do everything he could during his year of office to follow the example set by his predecessors; and he hoped that the Mansion House would be in the future as it had been in the past—the home of that great enterprise. Whenever it was possible, he should be glad to preside at the meetings of the Council.

The report of the Council was then read, and ran as follows:—

The fifteenth year of collecting this Fund is noteworthy as being the Jubilee year of the reign of Her Majesty Queen Victoria. On Dec. 13th, 1886, by resolution of the constituents in annual general meeting assembled, the Council for 1887 was elected; and at the same meeting the usual invitations to co-operate in the collection of the Fund for 1887 were ordered to be issued to the representatives of all congregations within the metropolitan area. The Council met on Jan. 27th, 1887, under the presidency of Sir Reginald Hanson, Bart., LL.D., F.S.A., Lord Mayor, and elected the Committee of Distribution, the General Purposes Committee, and the Special Committee for the Jubilee year. At the same meeting of the Council, Sir Edmund Hay Currie and Richard B. Martin, Esq., were re-elected honorary secretaries, and Henry N. Custance, Esq., secretary.

The committee appointed to make arrangements for Jubilee year, having held a large number of meetings, recommended the Council to continue the new departure of last year in holding public meetings in different parts of London during the week immediately preceding Hospital Sunday. Meeting were accordingly arranged, and speakers secured for resolutions previously prepared by the committee at the following places—viz.: The Mansion House, E.C.; St. Mary Newington, Parochial Hall, S.E.; Paddington Vestry Hall, W.; Hampstead Vestry Hall, N.W.; the Rink Hall, Blackheath, S.E.; Lambeth Palace Library, S.E.; Shoreditch Town Hall, E.; St. Andrew's Hall, Newman-street, W.; Kensington Town Hall, W.; The Wellington Hall, Islington, N.; Westminster Town Hall, S.W.; Stratford Town Hall, E.; and the People's Palace, Mile-end-road, E. The Presidents at the several meetings were—his Royal Highness the Duke of Cambridge, K.G., &c.; his Grace the Archbishop of Canterbury; his Grace the Duke of Argyll, K.G., &c.; the Right Hon. Sir Reginald Hanson, Bart., LL.D., &c., Lord Mayor; Very Rev. the Dean of Westminster; Lord William Compton; the Right Rev. the Bishop of Bedford; Sir William Plowden, K.C.S.I., M.P.; Major Ross, M.P.; the Rev. Walter Abbott, M.A., vicar of Paddington; the Rev. H. W. Barlow, B.D., vicar of Islington; John Meesom, Esq., Mayor of Stratford; and Henry Green, Esq.

The fund of 1887 has reached £40,607 7*s.* 8*d.*, as compared with £40,399 7*s.* 7*d.* collected in 1886, and with an average of £31,572 7*s.* 9*d.* in the last fifteen years. The Rev. Canon Fleming, of St. Michael's, Chester-square, again heads the list of contributors with £1028. The Rev. C. J. Ridgeway, of Christ Church, Lancaster-gate, comes next with £802 6*s.* 7*d.*, and the Rev. Dr. Forrest, of St. Jude's, South Kensington, is third with £802.

Years.	Amounts.	Congregations.
1873	£27,700 8 1	1072

The Committee of Distribution met on Feb. 1st, and determined the various forms and circulars to be filled up by the representatives of hospitals and dispensaries seeking to participate, in conformity with Law V., page 4, and on July 16th made the following report:—

Annual General Report of the Committee of Distribution to the Council of the Metropolitan Hospital Sunday Fund, 1887.

Your committee have the honour to recommend the payment of awards to the 158 institutions enumerated in the appendix to this report, being an increase of four since last year, and of fifty-three since the first awards were made in 1873. The total amount available for distribution, after allowing sufficiently for liabilities and the usual current expenses, is £39,125. Of this total, £37,525 is now recommended to 108 hospitals and 50 dispensaries. Four per cent. of the total collected—viz, £1600—is set apart to purchase surgical appliances, in obedience to Law XII. (page 5), in monthly proportions, during the ensuing year. Your committee recommend that all payments to the Fund after this date be carried to the credit of next year's fund. In compliance with an order of the Council, and for the special use of its members, Tables of Statistics have been prepared as usual, showing an analysis of the number of beds in hospitals, the cost of patients both at hospitals and dispensaries, the proportionate expense of management, as well as other valuable information, and copies are now sent to every member of the Council. The number of deputations representing committees of various institutions invited to confer with your committee, and to offer explanations on matters of apparently unsatisfactory character, was reduced from fourteen to nine. Five of these deputations attended, and in two cases your committee agreed to raise the award. Three institutions sent replies, but did not attend; and one made no reply. Three institutions which have been less than three years established, and hence could not comply with Law IV. (page 4) by furnishing balance sheets for three years, had to be refused. One application from an institution, being neither hospital nor dispensary, was also refused. Your committee regret to add that they have felt it their duty to make no award to one hospital, owing to unsatisfactory management. The committee have to express their great regret at the death of their colleague Mr. Lionel L. Cohen, M.P., prior to the completion of their work.

REGINALD HANSON, Lord Mayor, { President and Treasurer.

SYDNEY H. WATERLOW, Vice-President.

JOHN D. ALLCROFT, F. H. NORMAN, THOMSON HANKEY, W. SEDGWICK SAUNDERS, M.D., EDWARD C. HODGE, WM. MCARTHUR, ALFRED WILLETT.

On July 25th the Council was specially summoned to receive the report of the Committee of Distribution, and unanimously passed the following resolutions:—1. That the report of the Committee of Distribution for the year 1887 be, and is hereby, approved; and that the

Digitized by Google

several awards recommended be paid as soon as possible. 2. That the cordial thanks of this Council be, and are hereby, given to the chairman and the other members of the Committee of Distribution, for the labour they have bestowed in the preparation of the awards to hospitals and dispensaries, &c., and for the very efficient report of their proceedings. 3. That the cordial thanks of the Council be, and are hereby, given to the Right Honourable Sir Reginald Hanson, Bart., LL.D., F.S.A., &c., Lord Mayor, who, as President and Treasurer of this Fund, has, in this special year of Jubilee, given so much untiring attention and valuable time to ensure the success of the collections, and has thus enabled the Council to distribute a larger amount than in any previous year. 4. That the cordial thanks of the Council be sent to his Royal Highness the Duke of Cambridge, and to those noblemen, members of Parliament, and other gentlemen who so ably pleaded the cause of the hospitals and dispensaries of London in connexion with the Hospital Sunday Fund during the "Hospitals Week" of 1887. 5. That the cordial thanks of the Council be, and are hereby, conveyed to the editors of newspapers and to other members of the press, who gave valuable assistance in reporting proceedings at public meetings during the "Hospitals Week" of 1887 and also at other times, with a view to advance the success of this Fund. 6. That the Special (Jubilee year) Committee are hereby authorised to disburse to the several representatives of institutions who gave their time and services to further the success of the meetings during the "Hospitals Week," various amounts which in the aggregate shall not exceed £100.

The Council desire to express their thanks to the executors of the will of the late Dr. Wakley, Editor of THE LANCET, for the payment of his legacy, on June 1st, of £1000.

The working expenses have amounted to £1713 15*s.* 2*d.*, being 4·200 per cent. of the gross receipts, as compared with 3·942 per cent. last year, and with an average of 3·698 per cent. in the previous fourteen years; this increase has arisen from the special efforts of the Council in this Jubilee year.

The Council desire to express their thanks to the clergy and the ministers of all religious denominations for their valuable co-operation in pleading the cause of Hospital Sunday before their several congregations, with the marked success that has resulted this year; and also to Messrs. Hart Brothers, Tibbetts, and Co. for having again gratuitously audited the yearly accounts.

Letters of recommendation for in- and out-patients to the several hospitals and dispensaries, enumerated in the Appendix, are given, on their application, to the representative ministers of contributing congregations, and to others whose names appear printed in this report, so far as the supplies in the hands of the secretary will admit. It is an instruction to the secretary not to issue letters or recommendations except for the benefit of residents in contributing districts. In respect of applications for admission to convalescent hospitals, and for in-patients to chest hospitals, the name, age, and address of each patient must be given in writing.

Letters of recommendation for patients requiring surgical appliances are also given, in the following way, to the representative ministers of any contributing congregation for the use of its members and others whose names appear printed in this report:—1. Application must be made in writing to Mr. Custance, the secretary, giving the name, age, and address of the patient, and stating the nature of the appliance required. An estimate must also be sent, for the committee's approval, in all cases where the appliance asked for is likely to cost more than one guinea. 2. A proper form of recommendation will then be supplied to the members of the Council or to the minister of religion who makes the application. This recommendation will be available at the hospital or dispensary named thereon. 3. On presentation of the recommendation at the hospital or dispensary named, the secretary, or officer on duty, will inform the applicant which member of the staff will prescribe for the case, and see the appliance properly fitted. 4. The member of the staff who prescribes for the case will state where the required appliance is to be obtained. 5. As soon as the appliance has been properly furnished, and fitted to the satisfaction of the surgeon prescribing for the case, an invoice, with the cost shown, and bearing either the hospital or dispensary stamp or the initials of the secretary to vouch for its correctness, is to be sent to Mr. Custance, who will, in due course, make payment for the same. 6. Not more than £5 shall be paid for any one appliance, without the sanction of the vice-president and one of the honorary secretaries.—N.B. As the applications for surgical appliance orders are so numerous, the committee are only able to sanction a certain proportion from month to month.

By order. HENRY N. CUSTANCE, Secretary.

Mansion House, E.C., Nov. 28th, 1887.

The Right Hon. Sir Reginald Hanson, Bart., LL.D., &c., Lord Mayor, Treasurer, in account with the Metropolitan Hospital Sunday Fund.

Audited, and found correct, this 17th day of November, 1887.

(Signed) HART BROTHERS, TIBBETTS, & Co.,
Chartered Accountants, 14, Moorgate-street.

A statement of the number and various kinds of "surgical appliances" ordered from the Hospital Sunday Fund during the year 1886–7 is appended to the report. From this statement it appears that 299 trusses and 238 elastic stockings were distributed, whilst applications for spectacles, surgical boots, artificial eyes, abdominal belts, leg irons, &c., were responded to in considerable number.

Sir SYDNEY WATERLOW, in moving that the report be approved and ordered for publication, expressed a hope that the work of the Council during the year had been satisfactory, not only to the members who had taken part in it, but to the public at large. A larger amount had been raised during the year than on any previous occasion, which was no doubt in a great measure owing to the fact that the late Lord Mayor took (as the present Lord Mayor had promised to take) the deepest interest in the work, and did all he could, both inside the Mansion House and outside, to bring the Fund up to a sum which should be fairly creditable to the city and to the metropolis. He could not move the resolution without calling attention to a part of their work which, as many members would recollect, they had some difficulty in arranging—viz, the distribution of surgical appliances. More than 1500 persons had been relieved in that way without trouble or effort of their own beyond that of making known to the medical man or the minister of the district that they wanted such appliances. They had thus been relieved of the cruel work of running about from one end of the metropolis to the other to get the requisite number of letters, thirty or forty being sometimes needed before they could obtain the necessary relief. When it was remembered that so many persons had been thus relieved by means of the small sum set apart for the work, it would, he thought, be generally acknowledged that that part of their scheme had been worked satisfactorily. They had, of course, had many more applications than they could meet; but they had done their best to relieve those cases that had been recommended by ministers who had preached for the

Digitized by Google

Fund, and whose recommendation it was thought was entitled to the greatest consideration, since they only sent in the names of those with the details of whose cases they were thoroughly acquainted.

The motion, having been seconded, was unanimously agreed to.

The following gentlemen were recommended for appointment to fill vacancies on the Council:—Rev. S. B. Burnaby, Hon. and Rev. Carr-Glynn, Sir Reginald Hanson, Mr. A. L. Cohen, Mr. C. G. Montefiore, Alderman Whitehead, and Archdeacon Richardson.

The LORD MAYOR said he regretted that it would be impossible to hold the annual meeting at the Mansion House, as the repairs and decorations it was undergoing would not be completed in time; but arrangements had been made for holding it in the Old Council Chamber at the Guildhall.

Sir E. HAY CURRIE moved that the meeting be held on Monday, Dec. 12th, at 3 o'clock P.M. He did not know that there was any burning question to bring before the meeting, but it was important that it should be held, as it gave their constituents the only opportunity they had of expressing themselves on the general policy of the Hospital Sunday Fund.

Dr. GLOVER seconded the motion, which was unanimously adopted.

The Bishop of LONDON moved that Sunday, June 10th, be selected as Hospital Sunday for 1888.

The Rev. Canon FLEMING seconded the motion, which was adopted.

Sir E. HAY CURRIE, in moving a vote of thanks to the Lord Mayor, said that the action taken by his lordship and his predecessors proved that the Hospital Sunday Fund was no mushroom institution. It had borne the heat and burden of the day for fourteen years, and had increasing claims upon the public support.

The motion, having been seconded, was unanimously agreed to.

The LORD MAYOR, in acknowledging the compliment, again expressed his regret that he was unable to receive the members at the Mansion House at the annual meeting, but he hoped to have that honour under more favourable circumstances.

The proceedings then closed.

SANITARY LEGISLATION IN ITALY.

A FEW days hence the Senate of the Italian kingdom will be engaged in discussing the new code for the better surveillance of public health throughout the peninsula. Pending the official issue of that important enactment, the following details as to its scope and bearing will not be without interest.

In the Home Department there will be created a General Board of Public Health, and, conjoined with this, an office of sanitary technology, with laboratories fitted up for every requirement of sanitary inspection. In every province of the kingdom there will be a provincial medical officer (*medico provinciale*), invested with sanitary functions, in addition to the present Provincial Council of Public Health (*Consiglio Provinciale di Sanità*). In every commune not the chief town of the province the syndic will have a sanitary advising assessor (*consiglier sanitario*). Each commune will also have a medico-chirurgical and zoo-iatrical staff, consisting of physicians, surgeons, veterinarians, and pharmacists. Communes with over 10,000 inhabitants will have a municipal medical office to provide for the efficient working of the hygienic and sanitary service. Under its second chapter the Code defines the functions of the General Board of Public Health, which board will exercise authoritative surveillance over the health interests of the communes, including their sanitary offices, over public works involving sanitary risks, over rice-culture, and such like. Its third chapter treats of the powers invested in the Superior Board of Health for deciding questions in dispute between the communal and the sanitary authorities, and between these latter and the provincial health officer. The fourth chapter takes cognisance of the newly instituted *medico provinciale* and his functions. These will have a wide range, and will include questions of hygiene, medicine, and pharmacy. The *medico provinciale* is nominated by Royal decree, after due certification by competitive trial of his qualifications. The seventh chapter defines the functions of the Communal Sanitary Council, which is nominated by the prefect and selected from among the medical practitioners in the commune. Its duration will be of three years, and it may be re-elected. It exercises surveillance over the interests, hygienic and sanitary, of the Commune. The eighth chapter describes the functions of the medico-chirurgical, pharmaceutical, and obstetrical staff, or *assistance publique*. The ninth chapter dwells on the zoo-iatric staff, and provides that every commune, chief provincial town, *arrondissement*, or locality having over 20,000 inhabitants shall have one or more veterinary surgeons; while every other locality not coming under the above category as to size shall have one veterinary surgeon, either by itself or conjointly with a neighbour locality. The tenth chapter defines the duties of the sanitary officer. The Code, which is introduced by the Prime Minister, Signor Crispi, also deals with the hygiene of soils and dwelling-houses, of beverages (natural and artificial), and of the lower animals, besides giving practical directions as to a sanitary police service.

The Italian Senate is at present, through a committee appointed *ad hoc*, considering the provisions of the Code, preparatory to a general discussion on the committee's report. The discussion will have much interest for the English sanitarian, whose experience, as embodied in official and non-official publications, has been largely utilised for this new legislative enactment, so long expected and so imperatively required.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in the Pwllheli Rural District, by Dr. PARSONS. This district in Carnarvonshire is, apart from the old borough of Nevin, mainly of a scattered character, and during the past ten years its diphtheria death-rate has been more than three times that for England and Wales generally. In 1886 there were 24 reported cases and 7 deaths; but owing partly to the absence from the district of the medical officer of health at the time of the inspection, and to linguistic difficulties in this remote part of the Principality, no special information was forthcoming bearing upon the etiology of the disease. Incidentally the general sanitary circumstances of the district came under review; and it was found that although on account of the natural configuration of the district and its scattered character no public works were called for, yet that the authority had been very slow in dealing locally with questions of water supply, drainage, and other matters. Notably, damp sites and filthy surroundings of houses were observed, many of the dwellings being in a bad state of repair and needing adequate means of ventilation; and it was felt that conditions such as these had, in all probability, had some distinct influence in the causation and in the observed increasing severity of the disease.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

West Sussex Combined District.—Dr. Kelly's report relates to the health during the past year of eleven different districts, and in each case the mortality at groups of ages, the infant mortality, and the effect of season on health and in the death-rate are considered. The improvements as to water supply and drainage are set forth; the work done under the dairies and cowsheds order is also explained; and in certain instances such exceptional occurrences as the prevalence of enteric fever at Lancing College, which occurred in July, 1886, and on which we commented at the time, are discussed in detail. On the whole combined area the death-rate for 1886 was 16·4, and the birth-rate 27·8 per 1000 living, the former being somewhat higher than it has been since 1876, when it stood at 16·5. The zymotic class of diseases caused deaths at a rate of 2·4 for every thousand living; but, in discussing this class, Dr. Kelly wisely reminds his authorities of the very dissimilar character of the diseases which have been grouped together in it, some being the current catching infections, such as small-pox and scarlet fever; others not at all catching in the same sense, such as

Digitized by Google

diarrhœa; and the various members of the group differing almost as far as it is possible in point of causation. The whole record, with its excellent meteorological mortality and other tables, forms a further volume of a very complete sanitary history of the districts included within the combination.

Bolton Urban District.—In common with many towns, Bolton exhibited last year a higher death-rate than usually, the rate being 23·1 per 1000. During the year the infectious hospital had a satisfactory history, and its increasing popularity was shown by the admission into it of no less than 208 patients. Of these, 193 were cases of scarlet fever, amongst whom only 2 died. A further addition to the sanitary organisation of the borough has been the provision of a Washington Lyon disinfecting apparatus. The record of sanitary work carried out is a satisfactory one, and amongst the matters receiving constant and increasing attention is the state of dairies, cowsheds, milkshops, and bakehouses.

Huddersfield Urban District.—Huddersfield has maintained a comparatively small death-rate for some years, that for 1886 having been 19·5 per 1000. During the year 39 cases of small-pox came under observation, and the control of the disease was largely effected by the aid of hospital isolation. An unusual number of cases of diphtheria were also noticed, 12 attacks terminating fatally. Of scarlet fever 370 cases occurred, and Dr. Cameron expresses the opinion that had the hospital provision sufficed to grapple properly with the beginning of the epidemic in 1885, the prevalence of 1886 with its 33 deaths might have been avoided. One inspector is now almost exclusively engaged in the systematic visitation of houses with respect to their sanitary state, a duty the importance of which it would be difficult to exaggerate. In the general summary of improvements effected, it is shown that the change for good has been most marked as regards the diseases which it has been possible to isolate, whereas in infectious cases where no such practice has been possible improvement has been much less obvious.

Ilfracombe.—Dr. Slade-King opportunely reminds his readers of the advantages which Ilfracombe affords as regards climate. Thus, whilst last winter the thermometer was on several occasions nearly down to zero in many parts of England, only two degrees of frost were registered at Ilfracombe, and that on one date only. The mean temperature during December last was 42·7°F., with a range of 8·2°, and the record given of the flowers which blossomed in open air last February suffice to prove the comparative mildness of the climate. The death-rate for 1886 was 14·7 per 1000, including visitors, and 13·2 on the resident population.

Glanford Brigg Rural District.—The ironstone villages of this district have an unenviable notoriety for excess of death. Thus, in 1886, whereas the rate of mortality under one year was 13 per cent. of registered births in other parts, it reached 20 per cent. in those villages. Diphtheria was fatal during the year, and it was found necessary to close the schools before the disease could be arrested. Amongst the directions in which future work is needed we note the absence of good drinking water in many of the villages, and in some instances Mr. Moxon advocates the extension of rain-water storage to meet an admitted difficulty in procuring a supply. Some improvements have been effected in the matter of sewerage, and the inspector of nuisances supplies a good list of work done in his department. The general death-rate on a population of about 31,000 was 17·3 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5726 births and 4158 deaths were registered during the week ending November 26th. The annual rate of mortality in these towns, which had been 20·0 and 21·1 per 1000 in the preceding two weeks, further rose last week to 23·5. During the first eight weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, and was 0·8 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·8 in Leicester, 16·1 in Wolverhampton, 16·5 in Cardiff, and 16·9 in Norwich. The rates in the other towns ranged upwards to 29·6 in Halifax, 30·6 in Preston, 31·6 in Newcastle-upon-Tyne, and 34·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 402 and 404 in the preceding two weeks, rose last week to 480; they included 126 from scarlet fever, 115 from whooping-cough, 92 from measles, 44 from "fever" (principally enteric), 44 from diphtheria, 41 from diarrhœa, and 18 from small-pox. No deaths from any of these zymotic diseases were registered last week in Wolverhampton or in Cardiff, whereas they caused the highest death-rates in Sheffield, Bolton, Bradford, Derby, and Blackburn. The greatest mortality from scarlet fever occurred in Bolton, Sheffield, Preston, Bristol, Blackburn, and Birkenhead; from measles in Blackburn, Birmingham, Bolton, Bradford, and Derby; from whooping-cough in Norwich and Oldham; and from "fever" in Preston. The 44 deaths from diphtheria in the twenty-eight towns included 31 in London, 3 in Manchester, and 2 in Portsmouth. Small-pox caused 16 deaths in Sheffield, 1 in Bristol, and 1 in London, but not one in any of the twenty-five other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 13 patients on Saturday last, against 16 at the end of the previous week. The number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital at the end of the week was 2764, against 2737 on the previous Saturday; the cases admitted were more numerous than in the previous week. The deaths referred to diseases of the respiratory organs in London, which had been 506, 438, and 461 in the preceding three weeks, further rose last week to 560, and exceeded the corrected average by 90. The causes of 89, or 2·1 per cent., of the 4158 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Preston, and in four other smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·9 and 22·0 per 1000 in the preceding two weeks, further rose to 23·5 in the week ending Nov. 26th; this rate corresponded with the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·8 and 19·4 in Dundee and Perth, to 24·4 in Glasgow and 25·8 in Paisley. The 580 deaths in the eight towns last week showed a further increase of 39 upon the numbers returned in recent weeks, and included 30 which were referred to whooping-cough, 13 to measles, 12 to "fever" (typhus, enteric, or simple), 11 to scarlet fever, 8 to diarrhœa, 4 to diphtheria, and not one to small-pox; in all, 78 deaths resulted from these principal zymotic diseases, against 74 in each of the preceding two weeks. These 78 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·4 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 26 in each of the preceding four weeks, increased last week to 30, of which 15 occurred in Glasgow, 6 in Greenock, and 3 in Edinburgh. The deaths from measles, which had slowly increased in the preceding five weeks from 5 to 8, further rose last week to 13, and included 5 in Edinburgh and 4 in Dundee. The deaths referred to "fever" rose from 6 and 11 in the previous two weeks to 12, and included 7 in Glasgow, 2 in Edinburgh, and 2 in Paisley. The 8 deaths attributed to diarrhœa showed an increase of 2 upon the number in the previous week. The 11 fatal cases of scarlet fever, on the other hand, had declined from 17 and 16 in the previous two weeks to 11; of these 3 occurred in Dundee, 2 in Glasgow, 2 in Edinburgh, and 2 in Leith. The 4 deaths from diphtheria also showed a decline from recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 107 and 144 in the preceding two weeks, further rose last week to 156, and were 31 above the number returned in the corresponding week of last year. The causes of 75, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 31·0, 32·1, and 34·6 per 1000 in the preceding three weeks, declined again to 33·8 in the week ending November 26th. During the first eight weeks of the current quarter the death-rate in the

Digitized by Google

city averaged 29·9 per 1000, the mean rate during the same period being but 19·7 in London and 19·2 in Edinburgh. The 229 deaths in Dublin last week showed a decline of 5 from the high number in the previous week; they included 11 which were referred to scarlet fever, 8 to measles, 6 to whooping-cough, 3 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 2 to diarrhœa, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 45 and 29 in the preceding two weeks, rose again last week to 33; they were equal to an annual rate of 4·9 per 1000, the rate from the same diseases being 2·8 in London and 2·6 in Edinburgh. The fatal cases of scarlet fever, measles, and whooping-cough showed an increase upon the numbers returned in the previous week, while the deaths referred to "fever" and diarrhœa were less numerous. The 3 deaths from diphtheria corresponded with the number in the previous week. The deaths of infants were less numerous than in the previous week, while those of elderly persons showed a further increase. Seven inquest cases and 5 deaths from violence were registered within the city; and 55, or nearly a fourth, of the deaths occurred in public institutions. The causes of 45, or nearly 17 per cent., of the deaths in the week were not certified.

THE SERVICES.

WAR OFFICE.—Grenadier Guards: Surgeon William Campbell, M.B., from the Scots Guards, to be Surgeon-Major, in succession to Brigade Surgeon A. G. Elkington, retired (dated Nov. 5th, 1887).—Scots Guards: Surgeon Robt. Ashton Bostock, Medical Staff. to be Surgeon, vice W. Campbell, M.B., promoted into the Grenadier Guards (dated Nov. 30th, 1887). Army Medical Staff: Surgeon-Major John Albert Anderson, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon (dated Nov. 30th, 1887).

ADMIRALTY.—Staff Surgeon Solomon Kellett has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Nov. 25th, 1887). In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Solomon Kellett has been placed on the retired list of his rank (dated Nov. 25th, 1887).

The following appointments have been made: Staff Surgeon C. C. Gooding, to the *Agamemnon;* Surgeon L. H. Kellett, to the *Rover;* Surgeon J. A. Vasey, to the Portsmouth Division of Royal Marines; Surgeon E. A. Spiller, to the *Duncan;* Surgeon R. A. Fitch, to the Royal Marine depôt at Walmer, temporary; Surgeon J. L. Thomas, to the *Britannia,* temporary; Mr. Charles F. Downman to be Surgeon to Her Majesty's Coast Guards for Burnham and Roach River Stations; and Mr. Denis Hassett to be Surgeon and Agent at Kilmore.

RIFLE VOLUNTEERS.—13th Lancashire: Acting Surgeon W. Anderton resigns his appointment (dated Nov. 26th, 1887).

Correspondence.

"Audi alteram partem."

SIR JAMES PAGET'S "MORTON LECTURE" ON CANCER AND CANCEROUS DISEASE.

To the Editors of THE LANCET.

SIRS,—Those who, like myself, listened to Sir James Paget's recent lecture at the Royal College of Surgeons must have felt no less charmed with its eloquence than with its philosophy. But being desirous of instituting a scientific inquiry into the origin of cancer—which term I hold should be regarded as synonymous with "malignant disease"—I was disappointed that Sir James, instead of dispelling the mist which surrounds many of the phenomena of cancer, should, in my humble judgment, have added fuel to a controversial topic, first, by declining to recognise certain truisms, and, secondly, by introducing a number of side issues, which must seriously complicate the main question.

Sir James has purposely declined to express in unequivocal language any tangible opinion on the nature of cancer, but the report of his very able lecture will leave no room for doubt in the minds of those who read it that he considers cancer to be a blood disease and of micro-parasitic origin. Unprepared at present to refute Sir J. Paget's theory, I must content myself by saying that what observations linked together by him in a particular manner may appear in favour of it, will, if viewed from a different standpoint, oppose it. *In limine,* I go further than Sir James, and define cancer or malignant disease as a distinct focus or growth, whose component cells have arisen from normal cells, and which begin to infiltrate and consume healthy adjacent cells, the new growth sometimes generalising by the lymphatic and sometimes by the vascular system. Such is cancer regarded from its clinical aspect, and I submit that the disease is a distinct entity, clearly distinguished from every other pathological condition with which we are acquainted; this definition, further, separating the malignant from the non-malignant tumours. Sir J. Paget rightly remarks that the space between innocent tumours and cancers is filled with examples of intermediate forms; but if we pursue his reasoning a little further, the isolable fatty tumour merges into the ill-defined fatty tumour, and thence into ordinary adipose tissue, which is a normal constituent of the body, and, in common with all other normal tissues, has developed from a parent cell—the human ovum.

In lectures which I delivered at the Cancer Hospital in March, 1886,[1] I endeavoured to substantiate the local theory of the origin of cancer. Let me now say that from that time to this I have not seen a single case of cancer the occurrence of which could not be explained by some source of local irritation. The drawing exhibited here shows an

example of symmetrical epitheliomatous growths invading the eyelid. Sir James Paget and his school will consider this an instance in favour of the "constitutional" or "blood" theory, but to me it seems only a rare example of cancer occurring by two distinct foci in *parts which, being symmetrical,* have been exposed to the same source of local irritation. Whilst describing cancer as local in its origin, and maintaining that it should be classified as a local disease, it is not antithetical to admit the hereditary element as a factor in its production—e.g., that congenital phenomenon, the supernumerary digit, is typically a local condition proved to depend upon hereditary transmission.

Since this or like examples might be shown to descend from parent to offspring, I cannot believe that such transmission is effected through the agency of the blood, but through the impregnated ovum, from which every cell in the body of the offspring is ultimately formed, and this appears the explanation of the "numerous cases in which the cancer in the offspring is not in the same part as it was in the progenitor," every cell in the offspring inheriting the predisposition from the progenitor, but the disease beginning only at a focus ultimately exposed to a superadded excitation. Since my lectures were reprinted, by your courteous permission, from THE LANCET in a pamphlet form, I submitted them to Sir W. Gull, who very kindly favoured me with the following terse exposition of his views on the subject:—

"As the ovum differentiates into organs and the parts of organs, there is carried the hereditary force for good and for evil. Hence the local characteristics of the individual, expressive of the stock from which it came (heredity). The constitutional tendency is, therefore, *expressed locally,* as the voice of a man is that of his family, but this depends upon the structure of the larynx. Cancer, as this would

[1] Cf. THE LANCET, 1886, vol. i., pp. 682, 825.

Digitized by Google

lead us to believe, though in a sense inherited, is so only from the local disposition of certain parts. Practically, therefore, it begins locally, and may and must be thought of in its first occurrence in the system as a *local disease*."

Finally, whilst disinclined to join issue with Sir James Paget upon every point, his statement that we have not yet found a method for either the prevention or the cure of cancer cannot be allowed to pass unchallenged, for instances in which the disease has been cured are familiar to most practitioners; and though there is no common method applicable for the prevention of all kinds of cancer, there are recognised principles to be adapted to many of its varieties. As examples, let me cite the premonitory induration of the tongue or lips in elderly subjects caused by irritation from the stumps of teeth, or by smoking, which will often spontaneously resolve upon removal of the exciting cause. Leucoma or psoriasis of the tongue, dependent upon local irritation coupled with syphilitic taint, may be resolved by antisyphilitic treatment sedulously carried out. Where cancer is presumed to be about to commence in the scrotum of a sweep, change of employment and cleanliness should be insisted upon, and suitable local treatment employed. *Cessante causâ, cessat effectus.*

I am, Sirs, yours faithfully,

CHARLES E. JENNINGS, F.R.C.S. Eng.

Upper Brook-street, Grosvenor-square, W., Nov. 19th, 1887.

"THE NATURE OF SMALL-POX."

To the Editors of THE LANCET.

SIRS,—The fact that Mr. Birdwood has had almost unequalled advantages for acquiring a special knowledge of small-pox naturally directs attention to his theory. Mr. Birdwood asks us to believe that the pocks in small-pox develop from spores adhering to the skin of the patient who has been exposed to a spore-laden atmosphere. And he asks us to believe this on the strength of two statements.

The first statement is that this hypothesis accounts for the distribution of the pocks. Those who have examined many cases of small-pox in the unvaccinated must have been struck by the copiousness of the eruption on the back as compared with the abdomen. And this difference is much more striking than the difference between the number of pocks on the exposed parts and on the back. But, according to Mr. Birdwood's theory, in the race for spores the face and hands should be first, and the rest nowhere.

The second statement is that "on the unprotected the number of pocks does depend on the circumstances of exposure." That would, if proved, be a very interesting fact. But much definite evidence must be brought forward before anyone can effect so revolutionary a change in the general belief. Few would positively deny that it is conceivable an unprotected person might be more seriously attacked by small-pox after nursing a hæmorrhagic case than after passing a discrete case in the street, but the general effect of small-pox experience on the minds of medical men is to bring about a strong belief directly opposed to Mr. Birdwood's. Instances of the severest confluent small-pox where the patient and his friends cannot even guess the source of infection are very common in small-pox hospitals, and everyone who has seen families brought into small-pox wards, sometimes in groups, must have noticed the remarkable variations in the severity of the different cases from one household. It is highly probable that unknown personal "idiosyncrasies" have far more to do with the character of the attack than have the circumstances of exposure.

Having thus seen objections to the acceptance of Mr. Birdwood's two statements in support of his theory, one may look at the arguments against it, and in favour of that which is usually accepted.

1. Small-pox, scarlet fever, typhus, measles, and chicken-pox all begin with illness followed by eruption. As regards the *copiousness* of the eruption: scarlet fever rather prefers the neck, chest, and abdomen; typhus the sides of the chest and abdomen; measles the back; and chicken-pox the chest and back. Why should small-pox be classed by itself because it prefers the face, wrists, and back? The theory that the poison is spread by the circulation does not explain this preference, but neither does it explain the selections of the others. In this respect these maladies are all on a par, and one can find no reason for removing small-pox from acute febrile diseases.

2. In small-pox the initial fever is severe for two or three days before the pocks appear. Until an hour or two before the actual eruption no unusual sensation whatever is felt in the skin. Why then attribute so striking a general fever to an as yet non-existent irritation in the skin? The common theory keeps the cart behind the horse, and does not attempt to make the pocks account for a fever which precedes them.

3. In many cases of small-pox the line of pressure of a garter, waistband, brace, &c., is traced out by an extra number of pocks. The circulation theory explains this naturally, because a congestion occurs in such places when the pressure is removed, and it is easy to suppose that there would therefore be a great pock-formation. But on the spore-adhering theory these are the very parts where pocks should be fewest.

4. In many cases of hæmorrhagic small-pox the pocks are few, ill-developed, and never get beyond the early papular stage, whilst over nearly the whole surface of the body violent redness, rapidly becoming purple, shows the extraordinary skin hæmorrhage that takes place. In such cases the post-mortem examination reveals that singular distribution of internal hæmorrhages which is peculiar to small-pox, and of which the hæmorrhage into the substance of the wall of the pelvis of the kidney, not merely, as usually believed, into the cavity of the pelvis of the kidney, is the most striking example. To explain such occurrences on his theory, Mr. Birdwood must suppose absorption and subsequent circulation of the organisms, thus tacking the old theory on as an occasional necessary adjunct of the new.

5. When formerly small-pox virus was intentionally placed in a patient's skin, the process was followed in a day or two by the appearance of one or more papules. The patient then wandered into no spore-laden atmosphere, but awaited events in his room, and about eight days later a general crop of papules appeared. Are we to suppose that the primary papule used its central depression, like a volcano its crater, to pour forth spores which the patient then rearrested and developed into his general eruption? It is hardly necessary to suggest other points, such as the occurrence and locality of initial rashes. So great are the objections to Mr. Birdwood's theory, that one cannot but continue to class small-pox with the other acute febrile diseases, which it resembles in so many points; and also to confess, with Sir James Paget, that "we cannot tell why small-pox is especially manifested on the skin."

I am, Sirs, yours truly,

JAMES STRUTHERS, Jun., M.B., C.M. Aberd.

Lewisham, Nov. 1887.

NEPHRECTOMY.

To the Editors of THE LANCET.

SIRS,—I regret that I was prevented from attending the last meeting of the Royal Medical and Chirurgical Society to discuss Mr. Warrington Haward's interesting case of nephrectomy, as I had promised. It would seem from the youth of the patient, and from the fact that one kidney was healthy, the case was well selected and one eminently favourable for surgical interference; and those who have Mr. Haward's acquaintance know that in trusting to his manipulative skill the patient had secured one safeguard against the accidents inseparable from surgery. The ill result must therefore, I think, be attributed to the operation chosen. Two reasons are given for the choice of the abdominal operation in preference to the lumbar: (1) the mobility of the kidney; (2) its size. The first of these operators may for the future entirely disregard. The mobility of the kidney, so far from necessitating an abdominal operation, renders the lumbar operation much more easy to perform. In support of this, I may mention that two years and a half ago I removed through the loin a kidney full of stones, which dropped so low in the iliac region that the fingers could be pressed in between it and the ribs; and when the patient lay on the opposite side it fell across the umbilicus. This was the easiest nephrectomy I have yet performed. The second reason I am unable to gauge, as no measurements are given; but of this I am certain, that very much larger tumours may be removed by the loin than surgeons have been inclined to attempt, if they will adopt the oblique crucial incision I have always advocated. This consists of an oblique incision parallel with the last rib, and a finger's breadth below it, followed by a

Digitized by Google

vertical, corresponding to the margin of the quadratus lumborum, extending from the upper edge of the last rib to the iliac crest. Tumours containing fluid may be always reduced in size by tapping before being removed, and a large suppurating kidney should be drained before nephrectomy is undertaken. Experience has shown that the ureter, however thickened, causes no trouble, and may be left in the wound secured with a simple catgut ligature. The stitching of this to the surface must add a danger both immediate and remote. One speaker referred to a kidney so adherent that he thought it would be impossible to remove it from the loin. I believe a kidney, however adherent, may always be so removed, if the capsule be left behind. There is a patient leaving Guy's Hospital to-day quite well, whose left kidney I removed about five weeks ago. It had been suppurating for nine years, and was closely adherent to the colon and surrounding structures. To have removed it together with the capsule would have been certain death, but it was stripped out without much difficulty from within the capsule. I have now removed five kidneys in succession through the loin without a death, and this success depends not on the operator, but on the operation (which, speaking generally, should almost always be lumbar), and on a proper selection of cases suitable.

I am, Sirs, your obedient servant,

R. CLEMENT LUCAS, B.S., F.R.C.S.,
Senior Assistant Surgeon to Guy's Hospital.

Finsbury-square, Nov. 28th, 1887.

CHIAN TURPENTINE AND CANCER.

To the Editors of THE LANCET.

SIRS,—It is now some seven years ago since Professor Clay gave to the profession, through the medium of your journal, the welcome intelligence that at last a specific cure for cancer had been found in Chian turpentine; and I think it may without fear of contradiction be asserted that no remedy has had a fairer trial at the hands of his *confrères* or more grievously disappointed them. It is true that Mr. Clay endeavoured to get over the discrepancy by alleging the impurity of the drug used, but doubtless many like myself still continued their observations with the genuine article as supplied by Southall of Birmingham, to find the result still the same.

Notwithstanding the almost unanimous condemnation of the treatment, I find in a later paper of Mr. Clay's (THE LANCET, vol. ii. 1881, p. 1033) these words: "An enlarged experience, however, has confirmed the statements made in my original paper, and I have now the satisfaction of being able to declare that I have nothing to withdraw or to qualify as regards the statements I then made as the result of observation as to the effects of Chian turpentine in uterine cancer." From time to time he has favoured his professional brethren with repeated cures of cancer by this remedy, and even so recently as in your last week's issue three more examples are given. But what about the failures? In the interest of the public at large, such claims as Mr. Clay makes for Chian turpentine ought not to pass unchallenged by those who differ from him. Unfortunately, examples of cancerous disease are only too common upon whom this remedy (supplied, if necessary, by his own chemist) might be tested by a tribunal in whom the profession at large would have confidence, and the doubt once and for all resolved. If this drug came out of the ordeal triumphantly, then I feel sure there would not be a single dissentient to Mr. Clay occupying a position not inferior to Jenner or Harvey as one of the greatest benefactors of our species; but if, on the contrary, it is wholly useless as a remedy, then let it drop into a well-merited, and not too premature, oblivion.

I am, Sirs, yours truly,

Nottingham, Nov. 21st, 1887. GEORGE ELDER.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—With your permission I should like to say a few words in reply to Mr. Holmes' sweeping condemnation of the power possessed by the Council of Surgeons of electing to the Fellowship Members of twenty years' standing, two in each year. If as many as that, or more, should present claims arising from the work done during that twenty years, which claims are open to the investigation and criticism of the Council, I think it would be out of all reason to reject them on the ground of there having been no examination. How many of the Fellows who have gained their position in the only way Mr. Holmes would recognise, and have not been engaged in teaching or lecturing, would be able to retain it if, after twenty years of active practice, they were asked to undergo a second, similar to that which gave them their qualification? In my own case, the twenty years were spent in active and successful practice as a hospital surgeon, and though so many things practically useless were probably forgotten that an examination would have been difficult to pass, I yet believed that on assuming the position of consulting surgeon to the same institution I should not be asking too much in seeking to be recognised as a Fellow. So, I presume, thought the six gentlemen who, as already Fellows, signed my application. I believe in my own year mine was the only application, and I do not think these have ever been very numerous. But if they were to seek the honour, and were to present the same testimonials, I do not think the status of the Fellows would be so lowered by granting it, as Mr. Holmes seems to think.

I am, Sirs, your obedient servant,

Dec. 1st, 1887. J. H. GRAMSHAW, F.R.C.S. (by election).

PHARMACEUTICAL WEIGHTS AND MEASURES.

To the Editors of THE LANCET.

SIRS,—Since the introduction of the *cental* system (which, it may be surmised, is a step towards the future decimal system) into the Pharmacopœia, our weights and measures for surgery use have become troublesomely obsolete, so much so that it is with difficulty that the general practitioner who dispenses his own medicines can now do so without great waste of valuable time and much mental labour, in having to reduce his drachms and ounces to minims or grains. Solutions that were formerly prepared as so much per *drachm* or *ounce*, have become now so much per *cent.* It is a matter of surprise that the vendors of our weights and measures have not been sufficiently alive to the wants and requirements of the times, and sufficiently enterprising to supply a demand which is now seriously felt, for weights marked in grains, and measures in minims, in grades of tens and hundreds, instead of the old-fashioned and now virtually obsolete scruples and drachms, and fluid drachms with their halves. I would suggest that weights be now made according to the following gradation: 1, 2, 3, 4, 5, 10, 15, 20, 25, 30, 40, 50, 60, 100, 250, and 500; that minim measures be graduated on the left hand in drachms and half-drachms, and on the right hand be marked in grades of 10 minims up to 200, the first 100 having intermediate or 5-minim lines; that ounce measures be graduated on the left in ounces and half-ounces, the first half-ounce being subdivided into drachms, the second into two drachms; and on the right in 25, 50, and 100 minims; and that half-pint measures be graduated on the left in half-ounces and ounces, and on the right in grades of 100 minims. Some recognition of the old system, it is obvious, should be retained, and, although only recommended above for fluid measures, the requirements being greater, might also be adopted for the new weights; for instance, the 20 gr. weight might be stamped on the obverse side with the old symbol, ℈j; the 30 gr., ʒ ss.; the 40 gr., ℈ij., and the 60 gr., ʒj.

Were the above weights and measures possible to be obtained, and supplied through the ordinary channels, the labour and mental calculation saved to the busy practitioner would be immense.

I am, Sirs, yours truly,

Dovercourt, Nov. 1887. W. W. HARDWICKE.

THE PREVENTION OF PUERPERAL SEPTICÆMIA.

To the Editors of THE LANCET.

SIRS,—An ounce of fact is worth a ton of theory, gaseous or sagacious. Here is a single fact. It occurred in connexion with the case of extra-uterine gestation—a note regarding which appeared a fortnight ago, and also to-day in your columns. There could be no doubt as to septic

Digitized by Google

infection" (whatever the phrase stands for) being derivable from this patient, as she was septicæmic from decomposition of the placenta before its entire separation from the sac.

The next point is, that at one of the dressings, after separation had fairly begun, I removed, partly with dressing forceps partly with my fingers, a considerable piece of the decomposing placenta. My fingers were malodorous, showing their skin to have been soaked with micro-organism excrement and decomposition products, even after washing with a solution of perchloride of mercury, of moderate strength, in the room.

On going home I found a message from a midwife, asking me to help a case over for her with the forceps. I purified my hands in the course of about three minutes by using (1) soap and warm water with the nail-brush; (2) remembering how the stench of uterine cervical cancer is got rid of from the examining finger by turpentine, I washed my hands with turpentine, using the saturated nail-brush, then more soap and water, and finally rinsing in a solution of iodine. I washed my hands and instruments at the patient's in iodised hot water, and used fresh carbolic oil for lubrication. The patient, a multipara, got up, I am informed, as I did not require to see her after delivery, on the celebrated "ninth day," and made a perfectly good recovery, being now quite well.

A case of this kind (my own cases also at the time were non-septicæmic), where a good deal of vaginal manipulation took place, and where the fingers were, not half an hour before, in a septic state, answers various questions. It is not a merely providential escape from the production of what is pedantically and euphemistically termed "heterogenetic" septicæmia. "Rash!" some who have been wittily described as having "passed the climacteric," and so are unchanging in their views, will exclaim. I reject the imputation, for I have faith founded on fact in appropriate antisepticism properly performed.

I am, Sirs, your obedient servant,

ARCHIBALD D. MACDONALD, M.D. Edin.

Liverpool, Nov. 28th, 1887.

ELECTION OF ASSESSOR IN THE UNIVERSITY OF ST. ANDREWS.

To the Editors of THE LANCET.

SIRS,—I trust you will permit me to appeal to my fellow-graduates of this University in support of the candidature of Dr. John Duncan as the Assessor in the contest now going on. The high position which this gentleman holds, whether regard be had for his professional or his academic distinction, eminently qualifies him for the post, added to which, being on the spot, he will be enabled to attend all the University court meetings, which it will be wholly out of the power of his opponent, Viscount Cross, to do, as must be well known. I am, Sirs, yours obediently,

JOSEPH ROGERS.

Montague-place, Russell-square, London, Nov. 30th, 1887.

"IS CANCER CONTAGIOUS?"

To the Editors of THE LANCET.

SIRS,—I have been looking over my "Cause of Death Certificates" from March, 1883, to present date, and if you think the following cases, which have happened in my own practice, worth a corner in your valuable journal, I should like to bring them before the notice of the profession, as I think they might perhaps interest some of your many readers:—

E. G., aged 51 ...	Cancer of breast	... March, 1883.
H. H., aged 58 ...	Cancer of breast	... July, 1883.
J. D., aged 54 ...	Cancer of testicle and stomach	... Oct., 1884.
H. C., aged 56 ...	Cancer of uterus	... March, 1885.
G. W. B., aged 66 ...	Cancer of rectum	... Oct., 1885.
M. D., aged 55 ...	Cancer of uterus	... Jan., 1886.
T. C., aged 48 ...	Cancer of tongue	... Aug., 1886.
G. T., aged 74 ...	Cancer of rectum	... March, 1887.
E. C., aged 31 ...	Cancer of vagina and uterus	... April, 1887.
E. J., aged 58 ...	Cancer of breast	... May, 1887.
S. P., aged 65 ...	Cancer of stomach	... Sept., 1887.

The discharges from some of these cases were incessant and extremely offensive, in spite of the utmost cleanliness, and not only the rags, but the houses were saturated with what I may perhaps be allowed to call "cancer smell," strong carbolic acid lotion and other disinfectants being constantly necessary to enable the inmates to remain with the patient. In each of my cases, husbands, relatives, and nurses are all at the present time in perfect health. Some of them certainly complained occasionally of the smell going down their throats and "settling on their stomachs," as they called it, which was not surprising; but these symptoms readily yielded, at my suggestion, to a strong glass of brandy-and-water.

As there are always two sides to every question, would it not be well to collect evidence if we can, and see on which side the balance in favour of or against the contagion theory lies? I am, Sirs, yours faithfully,

L. NICHOLLS, M.R.C.S. Eng., L.S.A. Lond.

Bury St. Edmunds, Nov. 28th, 1887.

To the Editors of THE LANCET.

SIRS,—In a thesis written for the M.D. (Camb.) degree in June last, I made reference to the above subject; and, in support of my belief that malignant diseases are contagious, not only by immediate contact as mentioned by Sir Peter Eade, but also in a wider sense, I ventured to record the following, which occurred in my practice about two years ago: In a fen district, nine miles from any town or railway, and three from the nearest village, and with very few dwellings in it, three labouring men, all beyond middle age, living at separate houses and working together on the same farm, were each the subject of malignant disease within a comparatively few weeks of one another. Two of them had malignant disease of the stomach, and died at their own homes, the third had malignant disease of the œsophagus, and died at University College Hospital, where he was sent for surgical treatment. In the same thesis I wrote of the possible part played by the lymphatic system in the reception and ultimate development of the particular cell or cell products, which probably is the form the contagious material takes.

I am, Sirs, yours faithfully,

WM. GROOM, M.D. Cantab., &c.

Wisbech, Nov. 17th, 1887.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

A MEDICAL MAYOR FOR DURHAM.

MR. W. C. BLACKETT, a general practitioner in the ancient and cathedral city of Durham, has been elected Mayor. Mr. Blackett was apprenticed to the late Dr. Green of Durham, and is an old pupil at St. Thomas's. While assistant to Dr. Green, in 1849, during the cholera epidemic he rendered exceptional services in many places in the county of Durham. He afterwards settled in practice in Durham, and entered the municipal body, having previously pledged himself to keep aloof from all cliques and parties. After twelve years' service he left the Council, and at the end of nine years went back again. Then he retired to avoid the turmoil of a contest at a time when small-pox was prevalent, in order to prevent the spread of the disease. Mr. Blackett, who is in the prime of life, has reached now every honour in the power of his city to bestow, being Alderman, Justice of the Peace, as well as honorary Surgeon-Major to the 4th Durham Rifles. He is a keen sportsman and supporter of all manly games, such as cricket, quoits, football, boating, and swimming, as well as a benefactor to all local friendly societies.

FEBRILE EPIDEMIC IN THE NORTH.

For the last month an epidemic of a peculiar nature, whether as regards its frequency or some of its symptoms, has prevailed here. The patients are generally adults, taken ill, as a rule, with a rigor or slight chill; this is followed by feverishness and headache (the latter often severe), suggesting typhus. There is very little cough, and but trifling mucous irritation. Constipation is always present, and the high temperature continues for nearly a week. Muscular pains are complained of, and the head symptoms often include transient delirium. While the practitioner is perhaps considering what form of fever he has to deal with, the symptoms rather suddenly subside, but the convalescence is

Digitized by Google

slower than that observed after an ordinary cold. The absence of catarrh and sore throat in so many cases is remarkable. The affection is decidedly infectious, visitors paying one short call to a convalescent being often attacked within twenty-four hours. The weather in the north has not been at all severe.

A PROVIDENT MEDICAL ASSOCIATION FOR NEWCASTLE.

A meeting of practitioners to consider the desirability of founding a Provident Medical Association (on the lines of those existing in Leicester, Sunderland, Reading, and other large towns) was held in the library of the Royal Infirmary in this city last week. Dr. Philipson presided. The project gave rise to considerable discussion, but ultimately a resolution was agreed to to appoint a general committee of inquiry to see how far the proposed association was compatible with the existence of medical charities in the city, some of which are already to a great extent provident.

Newcastle-on-Tyne, Nov. 30th.

DUBLIN.

(From our own Correspondent.)

THE ENTRIES AT THE DUBLIN MEDICAL SCHOOL.

THE following is the official return of anatomical students for the present session:—

School.	Session 1887-8.	Session 1886-7.
Trinity College	219 ...	225
Ledwich	196 ...	217
Carmichael	165 ...	181
Royal College of Surgeons ...	134 ...	129
Catholic University	90 ...	80

From these figures it will be seen that, compared with last session, there is a decrease of six at Trinity College, twenty-one at the Ledwich, and sixteen at the Carmichael respectively. On the other hand, there has been an increase of five at the College of Surgeons, and ten at the Catholic University. Last year there were 832 anatomical students, this year 804, or a decrease of 28 on the general total.

PRECAUTIONS AGAINST SMALL-POX.

In consequence of the recent outbreak of small-pox in the south-east of Dublin, posters have been placarded about the city at the instance of the Public Health Committee of the Corporation. Various suggestions are made to the citizens, more particularly the poorer classes, urging the necessity of vaccination, and the desirability of sending every case of small-pox to the Cork-street Fever Hospital, so as to prevent the disease spreading. Other recommendations are also given, which have been found useful on similar occasions.

MERCER'S HOSPITAL, DUBLIN.

This inquiry has been adjourned to Dec. 12th, when it is believed that a basis of compromise between the contending parties will be brought before the governors for ratification.

ROYAL COLLEGE OF SURGEONS.

Dr. J. Wallace Boyce, late medical officer of Stillorgan dispensary, has been presented with an address, accompanied by a valuable gift, by the inhabitants of Stillorgan and its neighbourhood.

Mr. Rowland Scovell, M.B. T.C.D., has been elected house-surgeon to the Monkstown Hospital, co. Dublin.

Dublin, Nov. 29th.

BELFAST.

(From our own Correspondent.)

BELFAST ROYAL HOSPITAL.

FROM the report presented at the ninety-fifth annual meeting of the Belfast Royal Hospital, held recently, we learn that during the year ending August 31st there were 2238 intern patients (more than 100 in excess of last year), while in the extern department there were 15,237 patients treated. During the year Dr. Ross (physician), Dr. Byers (gynæcologist), Dr. Browne (surgeon), Dr. Nelson (ophthalmic surgeon), and Dr. J. A. Lindsay (assistant physician), having vacated office, were unanimously re-elected. The amount needed to secure Mr. Foster Green's generous offer to build a new wing to the Throne Hospital is not yet raised, but the Board of Management hope that before the year is ended the needful sum will be contributed. The small hospital already at work under Dr. Lindsay's medical care has been most successful. The hospital commenced the year with a deficit of £1048 8*s.* 2*d.*; at the close there is a balance against it of £581 8*s.* 1*d.* In addition to the sum of £354, the sum of £4100 has been invested during the year. From the medical and surgical staff report we gather that of the intern patients 965 were medical and 1273 surgical, while of the extern cases 2995 were medical and 12,242 were surgical. The intern and extern cases together numbered 17,445. Clinical instruction was given in the wards to 141 students during the winter, and to 82 during the summer session.

THE BELFAST MEDICAL STUDENTS' ASSOCIATION.

The opening meeting of this Association was held on the 22nd ult., when the President for the present session (Dr. J. A. Lindsay) gave a very interesting address. A lengthened discussion then took place in reference to the new regulations of the Royal University, which have given rise to the utmost dissatisfaction among the Belfast medical students. It was pointed out that these changes acted most unfairly in being retrospective, and attention was drawn to the fact that when students wrote to the officials of the University asking for explanations of these new changes, they received most oracular or diverse opinions. A resolution was passed unanimously that a sub-committee of the Association be appointed to take counsel's opinion as to the legality of these new regulations being enforced in the case of those students who entered before these changes were published. It is rumoured that further alterations in the regulations are about to be suggested to the Royal University by the Standing Committee. I need scarcely say that these perpetual changes made by the Royal University are causing many of those who in the north of Ireland were favourable to it to be utterly dissatisfied. They feel that matters will never be right until there is a University of Ulster, with its head-quarters in Belfast.

BELFAST NATURAL HISTORY AND PHILOSOPHICAL SOCIETY.

The session of the Belfast Natural History and Philosophical Society was opened in the Museum on Nov. 9th, when the President, Dr. Letts, Professor of Chemistry in Queen's College, delivered his inaugural address, before a crowded audience, on "Pasteur's Life and Researches." Dr. Letts gave a most admirable account of Pasteur's great scientific discoveries, and dwelt especially on his method of treating hydrophobia, a subject of interest to the audience, as the fact that several Belfast children bitten by a mad dog have been recently treated by M'Govern has directed attention to the matter.

EPIDEMIC OF PNEUMONIA AND SORE-THROAT.

A large number of cases of pneumonia have of late occurred in Belfast, several of which have proved fatal; while at the same time a great many cases of sore-throat, accompanied with high fever and great prostration, have been met with. It is believed by many that the prolonged dry season, by preventing the proper flushing of the drains, may have had something to do in the causation of these diseases.

THE BELFAST LYING-IN HOSPITAL.

An endeavour is at present being made to pay off the debt incurred in making some additions to this hospital. Mr. Foster Green has promised a handsome donation if all the money is raised by the beginning of the new year.

THE BELFAST MEDICAL SCHOOL.

We understand that the number of medical students is about the same this year as it was in the preceding session. There are 214 medical students at Queen's College, and about 130 at the Royal Hospital.

The annual dinner of the Ulster Medical Society was held on Wednesday evening, Nov. 23rd, in the Royal Avenue Hotel, the President (Dr. Ealer) in the chair. There was a large representation of the profession present, and amongst the guests were Surgeon-Major Grose and Dr. J. W. Moore of Dublin.

PARIS.

(From our Paris Correspondent.)

THE DEATH OF DR. CAUVY.

THE death of Dr. Cauvy, who was inoculated in the month of July at the Pasteur Laboratory, has given rise, as usual, to a difference of opinion between Pasteurians and non-Pasteurians. Some of the medical papers having inserted a short note stating the bare fact that Dr. Cauvy had succumbed to rabies after the preventive treatment, the *Bulletin Médical* publishes the extracts concerning this case from the register of the laboratory, together with the history of Dr. Cauvy's illness furnished by Dr. Sabatier. The first document is as follows:—"Dr. Cauvy (François), forty-six years of age, of Béziers (Hérault). Bitten the 29th of June, 1887, on the back of the first phalanx of the right first finger. Bite very superficial; had not bled. No treatment had been applied. The dog had bitten his master while he was endeavouring to force it to drink, and had put his hand in its mouth. Rabies was recognised by M. Gillis, veterinary surgeon at Béziers, and the dog died on the 3rd of July. Dr. Cauvy was treated from the 5th to the 15th of July." The history of the case is contained in the following letter from Dr. Sabatier to Professor Grancher:—

"Béziers, Nov. 4th, 1887.

"Most honoured Professor,—I feel it my duty to inform you of the very unexpected (*presque foudroyante*) death of a patient who I am told was treated by the anti-rabic inoculation. The patient in question was Dr. Cauvy, whom you may remember to have seen at the Pasteur Institute last July. Dr. Cauvy died on Nov. 3rd, and this is what I have gathered and observed concerning the short and terrible illness of our unfortunate *confrère*. Dr. Cauvy had no morbid antecedents. He was subject to migraine. His father was gouty, his mother died of cancer of the stomach, and his only son of tubercular meningitis. For about a fortnight Dr. Cauvy had been suffering from severe pain in the head, which did not prevent him fulfilling his duties. He attributed this pain to neuralgia, and treated it with small doses of antipyrin. On the evening of Nov. 2nd slight movement was remarked, and a few fits of guttural cough. On the 3rd, after a quiet night, Dr. Cauvy awoke, apparently well, and breakfasted as usual, according to his custom, upon coffee with a little bread. At a quarter-past seven he complained of violent pain in the head, and at once lost consciousness, and was seized with convulsions. I saw him at half-past seven: intelligence was abolished; the pupils largely dilated and insensible; respiration stertorous, difficult and irregular (*entre coupée*), the lips covered with a frothy bloody saliva. The four limbs were thrown about by tonic convulsions and contractured, the upper extremities in flexion, the thumb also flexed upon the palm of the hand, the lower extremities in forced extension. The pulse was strong, regular, and 70 to the minute. The temperature, in the absence of a thermometer, appeared normal. At half-past eight a flaccid paralysis of the four limbs replaced the contracture. At a quarter past nine the contracture and convulsions returned. The pulse and breathing ceased suddenly, and the patient died of syncope and asphyxia. These symptoms of bulbar apoplexy caused a great impression upon me, on account of the special circumstances attending the case. Should they be attributed to rabic intoxication, or are they to be considered as manifestations of this disease (bulbar apoplexy) in its last period? If not troubling you too much, I should be much obliged to know your opinion.

"I am, yours, &c.,

"11, Rue de la Coquille, Béziers." "DR. SABATIER.

M. Grancher has replied that in his opinion Dr. Cauvy did not die of rabies, and the *Bulletin Médical* remarks there was no symptom of this disease. Considering that Dr. Sabatier's letter must have been in Professor Grancher's hands on November 5th—that is to say, within two days of death—it is regrettable that Professor Grancher should not have thought it desirable to obtain a portion of the medulla and prove his assertion by inoculation.

HYPNOTISM BEFORE THE FRENCH LAW.

A schoolmaster has recently been charged, at the assizes of the Nièvre, with indecent assaults upon children under his care. At the previous sessions he had admitted the offence, but declared he had acted under the influence of an irresistible impulse. The court had in consequence postponed their decision, pending the medical examination of the accused. The medical witnesses have concluded that the case is one of hysteria, and that hypnotic sensibility being developed in a high degree, the subject is only responsible to a limited extent; and an intelligent jury pronounced a verdict of acquittal. It would be interesting to know whether these enlightened experts would have come to the same conclusion had the assaults in question been made upon their own children, and what would then have been their views on hypnotism.

TANACETIC AND TRUE RABIES.

After having in two previous notes communicated to the Academy of Sciences, which were duly reported in THE LANCET, (1) the biological effects of the essence of tanaisia in developing accidents of false rabies, compared with those of true rabies, after injections of this substance into the veins of rabbits, and (2) the preventive action of the hydrate of chloral in tanacetic and in true rabies—the author, Dr. Peyraud, has now come forward to make known the results of the experiments undertaken by him to verify the preventive action of the essence of tanaisia against true rabies. If, says the author, one submits to the action of the rabic virus of rabbits on which had been previously practised during six, seven, and eight days injections of the essence of tanaisia, the development of rabies is prevented in these animals. None of those to which this preventive treatment had been applied eight months ago, have been affected with rabies, whereas two rabbits that were inoculated with rabic virus without their having been previously subjected to the tanacetic injections succumbed to true rabies, one very rapidly, and the other more tardily. Whence the author believes that he has discovered in the essence of tanaisia an effectual remedy against true rabies.

THE MINERAL WATERS OF FRANCE.

The French have long been trying to be independent of the mineral waters of Germany, and the Hydrological Society of Paris has discovered that France is the only country in Europe which is capable of providing all that concerns thermal therapeutics. For instance, according to the above society, the waters of Royat perfectly represent those of Ems; those of Châteauneuf and Bourbon-Lancy are similar to the waters of Baden-Baden and of Wiesbaden, Chatel-Guyon can rival Kissingen and Marienbad, and Saint Nectaire replaces advantageously Niederbronn.

AN EPIDEMIC OF MEASLES.

An epidemic of measles has broken out at Lille, and is reported to be committing great ravages, particularly in the most populous districts of the town. Several fatal cases have occurred, attributable to the disease itself, or to other complications.

A PROPOSED NEW FACULTY.

Owing to the importance that the School of Medicine at Marseilles has attained, the Municipal Council of that city has petitioned the Government for permission to raise it to the rank of a Faculty.

THE BACILLUS OF CANCER.

In a paper read before the Medical Society of Berlin last Monday, and which is published in to-day's *Semaine Médicale*, M. Scheurlen gives an account of his experiments with the cancer bacillus. His conclusions are as follows: (1) There exists always in cancerous tumours a bacillus which can be isolated; (2) the spores of this bacillus are met with in all microscopical preparations of cancerous tissues; (3) inoculations upon animals with pure cultures of this bacillus always give rise to the formation of cancerous tumours; (4) there is consequently a causal relation between this bacillus and cancer. The bacillus in question is from 1·5 to 2·5 μ long and 0·5 μ wide. The spores are all of the same size, 1·5 μ by 0·8 μ, of ovoid shape, slightly green, and shining. The bacilli move like the weight of a pendulum round a centre.

ANTIPYRIN, A SPECIFIC FOR SEA-SICKNESS.

M. Emile Ossian-Bonnet, in a note to the Academy of Sciences, states that he has given antipyrin in sixty instances for the relief of sea-sickness, and with unfailing success. In most cases one gramme and a half is sufficient, and when

Digitized by Google

this is not enough, a second dose never fails to produce the desired effect. In exceptional instances where the medicine cannot be absorbed by the stomach on account of the vomiting, a hypodermic injection of one gramme suffices.

Paris, Nov. 30th.

QUARANTINE AND SANITATION AT TRIESTE.

(From our Special Correspondent.)

FROM a political, commercial, and strategical point of view, Trieste is certainly one of the most important ports in the Mediterranean. It is seeking to obtain a position similar to that which was once enjoyed by Venice. The railway lines and the passes through the Alps are so combined as to lead the natural flow of commerce to Trieste. Thus the size of the town, the number of its inhabitants, and also of commercial and other men who are constantly obliged to visit Trieste, are greatly increasing. Under such circumstances, the sanitary condition of this—the principal—Austrian port becomes more and more a matter of interest to all Europe. The fact that so great an outlet to the Mediterranean was, like Marseilles, invaded by the cholera is an illustration how the sanitary condition of such a port may affect the general comity of nations. There were in the Trieste district 893 cases of cholera recorded and 554 deaths. This, however, comprises a large outlying rural district, and the number of deaths is very much increased by the inefficient care taken of the inhabitants of small villages. Thus, though the mean proportion of deaths was equal for the Trieste district to 62·3, it equalled 76·1 in the village of Prosecco. The English colony, numbering 240 persons, completely escaped, though there were two English sailors who arrived ill in port.

At the town hospital Dr. Lustig adopted a system of treatment which, it is maintained, produced very good results. In two litres of an infusion of chamomile he introduced twenty grammes of tannin, from one to five centigrammes of corrosive sublimate, and from twenty to forty grammes of rum. These two litres were suspended a considerable height above the bed. At the end of a tube he fixed a long one of vulcanite, nozzled, which he passed up the rectum to a distance of ten or more inches. The contents of the enemata, by gravitation, thus gradually found its way into the intestines. The peculiarity of the treatment consisted chiefly of the considerable volume of liquid used and the great distance the nozzle was forced into the intestines. Both the evacuations and the sickness were checked by this method. The statistical data of the hospital establishes that 325 cholera patients were admitted. Three died before they could be seen, and twenty-five were in a dying condition. Fifty more were in an advanced stage of asphyxia. Nearly all the cases had already suffered more than once, and generally several days, before they were brought to the hospital. Ten were cases of dry cholera, with no evacuations, or very few. Of these 325 cases, 117 were treated with the enemata, as described above. Eighty-three recovered, while fifteen patients treated with subcutaneous injections of morphia all died.

The fear of cholera has led to the imposition of quarantine regulations, and in the Gulf of Trieste, since October, 1884, to May, 1887, no less than 1049 ships have been retained and placed under medical observation. The crews of these ships numbered 6671 persons, and there were also 288 passengers. The shipping thus detained amounted in tonnage to 93,400 tons. At the present moment ships coming from southern Italian ports are placed under observation for seven days. But if these same ships touch at Venice or any northern port before they reach Trieste, then they are not subjected to any sort of detention. Passengers coming overland may also enter the town without the slightest interference. The authorities themselves who carry out these quarantine regulations recognise that they are absolutely useless and vexatious. They are enforced solely to satisfy the ignorant sections of the native population, and to prevent panic.

The population of Trieste, now estimated at 154,000, shows a very high death-rate. It is now 37 or 38 per 1000, but has been known to reach the appalling figure of 52 per 1000. In 1886 the deaths from phthisis and from diseases of the respiratory organs were equal to almost 31 per cent. of the entire mortality; and this is attributed to the very trying winds that prevail at Trieste. From a sanitary point of view, the town is comparatively free from bad smells; the streets are well paved, many of them broad, and well opened to light and air. The drainage, of course, is very much below the English ideal, but still is much better than in many French towns that have a lower death-rate. Also, it should be remarked that the strictest measures are taken to prevent the spread of zymotic diseases. Medical men are obliged to report all infectious cases; and a board with the name of the disease is hung up on the street door of the house, and also on the door of the room where the patient is nursed. When the patient dies or is cured, the room is fumigated, then cleaned and white-washed, and the bedding either destroyed or taken to the town disinfecting stove. Considering these precautions, it is remarkable that the death-rate should remain so high; but, at the same time, it should be noted it is falling. For the first quarter of this year it amounted to 34·7, which is in any case better than the previous records. The supply of water was stated to be good, though of very hard quality. There is a very considerable amount of poverty, and, of course, the improper nursing of children accounts in a great measure for the high death-rate. It cannot be said, however, that health questions are neglected at Trieste, and there is every reason to anticipate a marked improvement in no distant future.

Trieste, October 30th.

Obituary.

CHARLES LOUDON BLOXAM, F.C.S.

WE regret to announce the death of Professor Bloxam of King's College on the 28th ult., at the age of fifty-six. The late professor had taught in the Chemical Department of the College for thirty-three years, having been appointed Demonstrator of Chemistry in 1854, Professor of Practical Chemistry in 1856, and Professor of Chemistry, in succession to Professor W. A. Miller, in 1870. He was also Professor of Chemistry for many years at the Royal Military Academy, Woolwich, and also at the Artillery Institute at Woolwich, and he held the latter appointment up to his decease. He was one of the ablest practical chemists in Great Britain, a fluent and able lecturer, and a most genial and pleasant colleague and teacher. In addition to some papers in the chemical journals, he was the author of "Bloxam's Chemistry," a new edition of which is about to be published, and of "Laboratory Teaching," a much-liked practical text-book, which has passed through many editions, and he re-edited and considerably improved "Bowman's Practical Chemistry." He was buried in Charlton Cemetery on the 1st inst.

HENRY JEPSON, F.R.C.S.

THIS gentleman, who died on the 23rd ult., was the youngest son of the late Rev. George Jepson, Prebendary of Lincoln Cathedral. He was born on Sept. 13th, 1797, and was consequently in his ninety-first year. His early education was conducted at the Lincoln Grammar School, and upon leaving it he entered as a student at the then united hospitals of Guy's and St. Thomas's. He took the degrees of M.R.C.S. and L.A.C. in 1819, and was subsequently admitted a Fellow of the College in 1863. After qualifying, he practised for a year or two at Colnbrook, and then removed to Hampton, where he soon attracted round him a large circle of friends, among whom may be numbered the late Sir Charles Clarke, Sir Andrew Halliday, Dr. Bright, and others. After a successful career he retired from active practice about four years ago. By the poor he was much beloved, and his death will be greatly felt by them. He was formerly district medical officer for the Kingston Union, and surgeon to the Kingston Dispensary and the Royal Humane Society.

THE salary of Dr. Gayton, the medical superintendent of the North-Western Hospital, has been increased from £400 to £500 per annum.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Nov. 24th, the following degrees were conferred:—

BACHELORS OF MEDICINE.—Arthur Lumsden Marshall, Clare; Richard Tanner Finch, Pembroke; Henry Skelding, Gonville and Caius; Cyril Hutchinson Walker, Jesus.

BACHELOR OF SURGERY.—Henry Skelding, Gonville and Caius.

SOCIETY OF APOTHECARIES.—The following gentlemen having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society in November, 1887:—

Beckett, Louis, Aberdeen-road, Highbury.
Bulger, Alfred James, Wellington-road, Dudley.
Bokenham, T. Jessop, Albury Lodge, Cheshunt.
Cunningham, John, Rudgrave-place, Egremont, Cheshire.
Flux, George Belben, Harley-street.
Fullard, John, Burnt Tree, Tipton.
Snape, E. A., St. Mary's Vicarage, Bury St. Edmunds.
Spong, Harry, Manston House, Crossgates, near Leeds.

The following gentlemen passed the Surgical portion of the examination.

Coulton, John James, London Hospital.
Cox, W. A. Spencer, Owens College, Manchester.
Cunningham, John, Liverpool School of Medicine.
Evans, Evan, St. Bartholomew's Hospital.
Hayward, Gerald Cobden, Middlesex Hospital.
Hicks, John Sidney, London Hospital.

VACCINATION GRANT. — Dr. Clarke, of Street, Somerset, has been awarded the Government grant for efficient vaccination in his district.

AT the annual meeting of the supporters of the Edinburgh Medical Missionary Society on the 24th ult., it was reported that during the past year the total income had amounted to £3957, and the expenditure to £5132.

AT the ninth annual festival dinner in aid of the funds of the East London Hospital for Children and Dispensary for Women held on the 24th ult., subscriptions amounting to £1739 were announced by the secretary.

THE Dental Hospital of London, Leicester-square, has received £1000 from its medical staff and lecturers, towards the £5000 required for the extension of the hospital, rendered absolutely necessary in consequence of the large increase in the number of patieuts.

HOSPITAL SATURDAY FUND.—At a meeting of the Board of Delegates of this fund held on the 26th ult., it was unanimously resolved that the sum of £10,000 be distributed among the London medical charities, the largest amount yet awarded.

NORTH LONDON UNIVERSITY COLLEGE HOSPITAL.—It has been decided to hold a fancy dress ball in aid of the funds at the Hôtel Métropole on the 9th of February next. A festival dinner with the same object will also take place at the same hotel early in the following May.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.—A meeting will be held at the rooms of the Society of Arts on Tuesday, Dec. 6th, at 4 P.M., to consider the report of the above Committee upon the medical attendance of the working classes, and the relation of provident dispensaries to hospitals. The meeting, we are informed, will be a public one, and a full and free discussion of the questions brought forward is desired.

HEREFORD INFIRMARY.—The ceremony of laying the foundation-stone of a new children's ward in connexion with this institution took place on the 23rd ult., in the presence of a large assembly of supporters of the charity. The new building, which is being erected at an estimated cost of £3000, will consist of two storeys, containing on the ground floor accommodation for sixteen beds, and on the upper floor dormitories and apartments for the nurses.

THE WILLIAM F. JENKS PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The first award will be made by the committee for the best essay upon "The Diagnosis and Treatment of Extra-uterine Pregnancy," as soon after January 1st, 1889, as may be practicable. The prize is of the value of $250, and is open to all the world. Papers for competition must be written in English, and be presented by the said date. The prize essay is to become the property of the College.

THE sixth annual meeting of the members of the West of Scotland Sanitary Association was held on the 25th ult., when highly satisfactory financial and general reports were presented and adopted.

ROYAL SOCIETY.—At the anniversary meeting of the members of the Royal Society on the 30th ult., the following, amongst others, were elected office bearers and members of the Council for the ensuing year:—Professor Michael Foster, secretary; Sir W. Bowman, Bart., Professor Arthur Cayley, Professor David Ferrier, and Arthur Gamgee, M.D., members of the Council.

PRESENTATIONS.—At a concert held at the Assembly Rooms, Talysarn, Carnarvonshire, on the 11th ult., in connexion with the Nantlle Vale Branch of the St. John Ambulance Association, Colonel Ruck in the chair, Mr. H. J. Roberts, M.R.C.S., of Penygroes, was presented with a handsome case of surgical instruments by the members of his "First Aid" men's class, and a valuable present of surgical works by the ladies of his "Nursing" class. Mr. J. H. Jones, M.R.C.S., of Talysarn, was likewise presented with a similar present of books by the ladies' "First Aid" class, in recognition of their services as gratuitous lecturers. Certificates were presented at the same time to a great number of successful pupils.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARMSTRONG, ARTHUR JAMES MACKENZIE, has been appointed Medical Superintendent of the Plaistow Hospital, Plaistow (Metropolitan Asylums Board).

BROOK, W. F., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin to St. Thomas's Hospital.

BULSTRODE, H. T., M.B., B.C.Cantab., L.R.C.P., M.R.C.S., has been reappointed Non-Resident House-Physician to St. Thomas's Hospital.

COLLINS, A. W., M.B.Vict., M.R.C.S., L.R.C.P.Lond., has been appointed Chloroformist to the Liverpool Royal Infirmary, vice W. M. Bristow, M.R.C.S., L.R.C.P., resigned.

COLMAN, HENRY, L.R.C.P.Lond., has been appointed Medical Officer for the Fifth District of the Devizes Union.

COOK, S. B., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin to St. Thomas's Hospital.

COOKE, E. W., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

CRISP, E. H., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Special Department for Diseases of the Ear to St. Thomas's Hospital.

DAY, DONALD D., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Medical Officer to the Norwich Dispensary, vice Firth, deceased.

FAWSSETT, F., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

GOODDY, E. S., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Special Department for Diseases of the Eye to St. Thomas's Hospital.

HILLIARD, R. HARVEY, M.D., F.R.C.S.E., has been appointed Honorary Surgeon to the Buckinghamshire General Infirmary.

HINNELL, J. S., M.R.C.S., L.S.A., has been reappointed Clinical Assistant in the Special Department for Diseases of the Eye to St. Thomas's Hospital.

HOBHOUSE, E., M.B., B.S.Oxon., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

HYSLOP, THEO. B., M.B., C.M.Edin., has been appointed Assistant Medical Officer to the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties, Lancaster, vice H. G. Taylor, M.D.Lond., deceased.

JONES, H. S., M.R.C.S., L.S.A., has been reappointed House-Surgeon to St. Thomas's Hospital.

KENYON, GEORGE HERBERT, M.B., C.M.Ed., has been appointed Medical Officer for the Hooton Pagnell District of the Doncaster Union.

NAIRN, R., L.R.C.P., M.R.C.S., has been appointed Non-Resident House-Physician to St. Thomas's Hospital.

ORD, W. W., M.A., M.B., B.S.Oxon., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

PARROTT, T. G., M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Surgeon to the Buckinghamshire General Infirmary.

PRIMROSE, ALEXANDER, M.B., C.M. Edin., has been appointed Pathologist and Chloroformist to the Paddington-green Children's Hospital, vice Gerard, resigned.

RICHARDSON, ADOLPHUS J., M.A., M.B. Cantab., M.R.C.P. Lond., M.R.C.S., has been appointed Physician to the Sussex County Hospital, vice Shadwell, resigned.

Digitized by Google

SMYTH, H. J., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

SOLLY, E., M.B.Lond., L.R.C.P., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

STABB, E. C., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear to St. Thomas's Hospital.

STACK, J. G. M.G., L.R.C.S.I., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator to the Gosberton District of the Spalding Union.

SUTHERLAND, GEORGE A., M.A., M.B., M.R.C.S., has been appointed House-Surgeon to the Paddington-green Children's Hospital.

TEBB, W. SCOTT, M.A., M.B.Cantab., L.R.C.P., M.R.C.S., L.S.A., has been reappointed Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

TONKING, J. H. L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Salary £80 per annum, with board and residence.

BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Resident Clinical Assistants.

HULL ROYAL INFIRMARY.—Honorary Dental Surgeon.

KILBURN, MAIDA-VALE, AND ST. JOHN'S-WOOD GENERAL DISPENSARY. Honorary Medical Officer.

KING'S COLLEGE, London.—Professor of Dental Surgery and Surgeon-Dentist to the hospital.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E. Junior Resident Medical Officer. Salary £30 per annum, with furnished apartments, board, attendance, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Assistant Physician.

NEWPORT (MON.) ODDFELLOWS' MEDICAL AID ASSOCIATION.—Medical Officer. Salary £140.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, E.—Junior House-Surgeon. Salary £30 for six months.

PONTEFRACT DISPENSARY.—House-Surgeon. Salary £130 per annum, with furnished rooms, coal, gas and attendance.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer. Salary at the rate of £60 per annum, with board and lodging in the hospital.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House-Surgeon.

ST. GEORGE, HANOVER-SQUARE, PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £100 a year, with furnished rooms and an allowance of £32 a year for servants' coals, and gas; also a percentage on members' payments, estimated to be £28 per annum.

ST. GEORGE'S HOSPITAL, Hyde-park Corner, W.—Assistant Physician.—Assistant Surgeon.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Junior Assistant House-Surgeon. Salary £50, with board, lodging, and washing.

SOUTHPORT INFIRMARY AND LOCAL DISPENSARY.—House-Surgeon. Salary £100 per annum, with board, furnished rooms, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

CORRY.—On the 27th ult., at Drumquin, co. Tyrone, the wife of William Corry, M.D., J.P., of a son.

DAUNT.—On the 25th ult., at Pierpoint, Lindfield, the wife of Elliot Daunt, M.R.C.S., L.R.C.P.Lond., of a daughter.

DE MÉRIC.—On the 26th ult., at Lyndhurst-terrace, Weymouth, the wife of Fleet-Surgeon E. V. De Méric, Royal Navy (retired), of a son.

MARRIAGES.

COLE—RAWLINGS.—On the 24th ult., at Christ Church, Surbiton, William Robert Newton Cole, M.D., to Ellen, eldest daughter of the late Rev. Jas. Rawlings, M.A., Rector of St. Pinnock, Cornwall.

MACVICAR—ROBERTSON-MACDONALD.—On the 7th ult., at the Parish Church, Northam, S. D. MacVicar, L.R.C.P.Ed., L.R.C.S.Ed., to Ada J., widow of the late W. D. Robertson-MacDonald, of Kinlochmoidart, and daughter of the late Thomas Littledale, of Highfield.

SUTTON—DUNSFORD.—On the 28th ult., at the Parish Church, St. Helier's, Jersey, Alexander Arthur Sutton, L.R.C.P. Ed., L.F.P.S. Glas., Army Medical Staff, to Annie Aubert, eldest surviving daughter of the late Gen. H. F. Dunsford, C.B., Bengal Staff Corps.

DEATHS.

DE CASTRO.—On the 23rd ult., at The Engadine, Torquay, Devon, James Cato De Castro, M.D., F.R.C.S., aged 63.

JEPSON.—On the 23rd ult., at Hampton, Henry Jepson, F.R.C.S., in his 91st year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, December 5.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Mr. J. Bland Sutton: Some cases of Abnormal Fissures about the Mouth.—Mr. Storer Bennett: An Extraordinary Example of Tooth Development.—Mr. Penfold: An Antiseptic, the Fluosilicate of Sodium.—Dr. Elliott: Some New Instruments.—Mr. Dennant: An Intercepting Bag in Nitrous Oxide Gas Administration.—Mr. E. Lloyd Williams: Pathology of Alveolar Abscess.

SOCIETY OF ARTS.—8 P.M. Mr. H. H. Statham: The Elements of Architectural Design. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Thorowgood: Cardiac Failure.—Dr. Stephen Mackenzie: Chyluria (with exhibition of a case). At 8 o'clock Dr. Mackenzie will give a demonstration of (1) Living Filariæ Sanguinis Hominis; (2) Some of the Developmental Changes in the Mosquito; (3) A Nematode Worm mistaken for Filaria Sanguinis Hominis.

Tuesday, December 6.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Specimens: Dr. Bedford Fenwick: Fatty Degeneration of Heart from Intra-abdominal Pressure.—Mr. Hutchinson: Arsenic Cancer.—Mr. Treves: Stricture of Intestine following Tubercular Ulcer.—Mr. W. Sibley: Tuberculosis in Birds.—Dr. F. C. Turner: Syringo-myelia.—Dr. Norman Moore: Carcinoma of Common Gall-duct.—Mr. Bull: Rare Form of Fracture of Lower End of Femur.—Dr. Ormerod: Partial Perforation of Skull-cap in Cerebral Tumour. Card Specimens by Messrs. Makins, Bull, Eve, and Dr. Hebb.

Wednesday, December 7.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-ST.—Operations, 9 A.M.; Saturday, same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Sir. J. Lister: The Present Position of the Antiseptic Question (Bradshawe Lecture).

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Malins, Mr. Bluett, and others. Dr. Herman: (1) A case of Eclampsia of Pregnancy, with Observations on the State of the Renal Function; (2) A case of Bright's Disease during Pregnancy.—Dr. Lewers: Note on the Post-mortem Appearances of a Phlegmon of the Broad Ligament.

SOCIETY OF ARTS.—8 P.M. Mr. P. L. Simmonds: The Chemistry, Commerce, and Uses of Eggs of Various Kinds.

Thursday, December 8.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M. Mr. T. H. Bickerton (Liverpool): Two cases of Fragments of Glass in the Anterior Chamber.—Mr. Marcus Gunn: Peculiar Foveal Reflex in connexion with Amblyopia in Myopia.—Mr. Quarry Silcock: Case of Large Exostosis of Orbit (and other cases).—Mr. Emrys Jones (Manchester): (1) An Unusual Complication after Subconjunctival Tenotomy of the Internal Rectus; (2) Persistent Hæmorrhage in the Anterior Chamber after Iridectomy for Chronic Glaucoma.—Mr. J. B. Lawford: On Congenital Defect of External Ocular Muscles.

Friday, December 9.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn: Clinical Society of London.—8.30 P.M. Dr. Barlow: Cases of Acute Enlargement of the Thyroid Gland.—Dr. Coupland: Hydatid Cysts of Left Lobe of Liver.—Mr. Owen: Hydatid Cyst on Convex Surface of Liver encroaching on Thorax.—Mr. Treves: Peculiar Mode of Rupture of a Hydatid Cyst, with case. Living Specimens by Mr. H. W. Allingham and Dr. Herringham.

Saturday, December 10.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Lectures
ON
FIBROID DEGENERATION AND ALLIED LESIONS OF THE HEART, AND THEIR ASSOCIATION WITH DISEASE OF THE CORONARY ARTERIES.

BY JOHN LINDSAY STEVEN, M.D.,
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; AND ASSISTANT TO THE LECTURER ON PATHOLOGY IN THE WESTERN INFIRMARY OF GLASGOW.

LECTURE I.

INTRODUCTORY.

THE condition of the heart wall, the consideration of which is to form the main object of the following remarks (viz., a development of what appears to the naked eye to be fibrous tissue in the midst of the muscle substance), is one which most English authorities would probably class under the term "chronic interstitial myocarditis," but which is frequently, though not invariably, to be referred to a cause quite different from that indicated by this term, implying as it does inflammatory action of a chronic kind. This fibrous transformation is most frequently met with in the left ventricle, may not be at all apparent either on the external or internal surface of the cardiac wall, and generally, though not invariably, occurs in association with widespread degenerative changes of the arterial system, obviously involving in most instances the coronary arteries of the heart. Besides the change just referred to, a more acute process of the nature of softening is also frequently met with in association with the same degenerative arterial changes or with embolism; and although the appearances of this acute condition are very different from those of fibrous change, yet the operating cause is so obviously similar that the two must frequently be regarded as different stages of the same affection, or as differing from one another only in degree. The details of the cardiac lesions thus briefly referred to, and of fatty degeneration as associated with arterial disease, will be described in due course, but in the meantime it will be necessary to give some account of our previous knowledge of fibroid disease of the heart.

HISTORICAL AND CRITICAL ACCOUNT.

The conditions of the heart wall (especially fibrous transformation[1]), which form the subject of these lectures, have long been described by special observers, but it is only of recent years that what appears to be, in most instances, their true pathological significance has been hinted at, and that much more on the part of continental than of English physicians. From the time of Morgagni downwards frequent references are to be found in medical literature to a fibrous condition of the heart-wall, apart from the lesions met with in connexion with the valvular apparatus. It is to be noted, however, that in many of the earlier writings reference is made to those conditions only where the fibrous change had advanced so far as to be visible on the surface, without requiring any special dissection of the muscular tissue for its exhibition. Thus Morgagni,[2] in his twenty-seventh letter, which treats of "Sudden Death from a Disorder of the Heart," article 17, after giving illustrations of calcareous plates in the substance of the heart, writes as follows: "For it is certain that the fleshy fibres of the heart themselves sometimes degenerate into a tendinous hardness. Albertini, therefore, saw in some bodies 'that the substance of the heart from the basis to more than half its extent had become tendinous, as it were, both in consistence and colour; which kind of metamorphosis I have it in my power to confirm, if there were any occasion, by an observation of my own.'" It will thus be seen that the condition has been recognised from the earliest days of pathological anatomy, and it is interesting in the light of modern research to observe that the term "degenerate" is used in the description of the change. It is not to be supposed, however, that the term necessarily meant the same to Morgagni that it does to us.

Towards the end of the last and the beginning of the present century medical literature abounds in communications on the subject of aneurysm of the heart, a condition which is very apt to follow upon the morbid condition at present under review. These records are therefore of great interest in the present investigation, and a few of the more important may be shortly referred to. Dr. Matthew Baillie[3] in his work on Morbid Anatomy describes a case of aneurysm of the left ventricle, and refers to the rarity of the condition. He explained the occurrence of the aneurysm by the muscular tissue at the apex being thin and weak, and so unable to resist the impulse of the blood against it. In 1817 Portal[4] published a long article on the subject of cardiac aneurysm, mainly from an etiological point of view. Among the different causes which he states as giving rise to aneurysms of the heart, the following may be mentioned: (1) the formation of false membranes inside and outside of the heart; (2) engorgement of the coronary arteries and veins; and (3) serous and purulent infiltrations. In the second of these it would seem as if we had a hint of the relationship which exists between a diseased condition of the coronary arteries and the development of cardiac aneurysm, but, so far as I can gather, the author simply refers to a dilatation of these vessels as one origin of aneurysm, and not to any nutritive change in the muscular tissue. About the same time important observations were published in France by Breschet[5] and Reynaud.[6]

Another very important paper in connexion with this subject from an historical point of view is that of Mr. John Thurnam on Aneurysm of the Heart.[7] Although, like the others just referred to, not directly bearing on the subject of fibrous transformation of the heart, the essay is very important from the fact that many of the cases were found to be associated with what is called "fibrous degeneration" of the heart-wall. With regard to the causation of the "fibrous degeneration" itself, the views adopted are pericardial adhesions and rheumatic inflammations. But nowhere is there found any allusion to the state of the coronary arteries as an etiological factor, nor are there any references to fibrous change as a morbid state of the heart-wall *sui generis*, and apart from aneurysm. Although in several of the cases the coronary arteries are mentioned as ossified, no opinion is expressed as to the probable relationship of this to the aneurysmal state. Interesting statistics are also given by Thurnam as to the situation of the aneurysm. Out of 74 cases, 58 were situated in some part of the left ventricle; and "the 67 aneurysms which occurred in the 58 cases, omitting one case in which this is not mentioned, may as regards situation be thus distributed: at or near the apex of the ventricle, 27; in different parts of the base, 21; in intermediate portions of the lateral walls, 15; in the interventricular septum, 3. ..... To conclude these observations on the situation of the aneurysms of the left ventricle, the only general conclusion that we can come to appears to be that the thinnest parts of its walls, or the apex and highest part of the base, are those which are much more frequently than any others the seat of the disease." This in general agrees with the observations of more recent writers and also with my own. It will thus be seen that in the record of Thurnam's cases we have a most important contribution to the literature of this subject from a pathological as well as from a historical point of view. In 9 cases the muscular tissue was the seat of more or less extensive "fibro-cellular degeneration," caused by inflammation it was supposed. If the disease was present to such an extent as to cause aneurysm in so many of the cases, we have strong reason for supposing that in its slighter manifestations, which are easily overlooked, it may occur much more frequently. The fibro-cellular degeneration, however,

[1] I use the terms "fibroid degeneration" and "fibrous transformation" as synonymous, and I think the latter is more scientifically correct. It is a real transformation into fibrous tissue with which we have to deal, so that the term "fibro'd" seems rather cumbrous.

SMYTH, H. J., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

SOLLY, E., M.B.Lond., L.R.C.P., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

STABB, H. C., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear to St. Thomas's Hospital.

STACK, J. G. M.G., L.R.C.S.I., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator to the Gosberton District of the Spalding Union.

SUTHERLAND, GEORGE A., M.A., M.B., M.R.C.S., has been appointed House-Surgeon to the Paddington-green Children's Hospital.

TEBB, W. SCOTT, M.A., M.B.Cantab., L.R.C.P., M.R.C.S., L.S.A., has been reappointed Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

TONKING, J. H. L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Salary £80 per annum, with board and residence.

BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Resident Clinical Assistants.

HULL ROYAL INFIRMARY.—Honorary Dental Surgeon.

KILBURN, MAIDA-VALE, AND ST. JOHN'S-WOOD GENERAL DISPENSARY. Honorary Medical Officer.

KING'S COLLEGE, London.—Professor of Dental Surgery and Surgeon-Dentist to the hospital.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E. Junior Resident Medical Officer. Salary £30 per annum, with furnished apartments, board, attendance, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Assistant Physician.

NEWPORT (MON.) ODDFELLOWS' MEDICAL AID ASSOCIATION.—Medical Officer. Salary £140.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, E.—Junior House-Surgeon. Salary £30 for six months.

PONTEFRACT DISPENSARY.—House-Surgeon. Salary £130 per annum, with furnished rooms, coal, gas and attendance.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer. Salary at the rate of £60 per annum, with board and lodging in the hospital.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House-Surgeon.

ST. GEORGE, HANOVER-SQUARE, PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £100 a year, with furnished rooms and an allowance of £82 a year for servants' coals, and gas; also a percentage on members' payments, estimated to be £28 per annum.

ST. GEORGE'S HOSPITAL, Hyde-park Corner, W.—Assistant Physician.—Assistant Surgeon.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Junior Assistant House-Surgeon. Salary £50, with board, lodging, and washing.

SOUTHPORT INFIRMARY AND LOCAL DISPENSARY.—House-Surgeon. Salary £100 per annum, with board, furnished rooms, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

CORRY.—On the 27th ult., at Drumquin, co. Tyrone, the wife of William Corry, M.D., J.P., of a son.

DAUNT.—On the 25th ult., at Pierpoint, Lindfield, the wife of Elliot Daunt, M.R.C.S., L.R.C.P.Lond., of a daughter.

DE MÉRIC.—On the 26th ult., at Lyndhurst-terrace, Weymouth, the wife of Fleet-Surgeon E. V. De Méric, Royal Navy (retired), of a son.

MARRIAGES.

COLE—RAWLINGS.—On the 24th ult., at Christ Church, Surbiton, William Robert Newton Cole, M.D., to Ellen, eldest daughter of the late Rev. Jas. Rawlings, M.A., Rector of St. Pinnock, Cornwall.

MACVICAR—ROBERTSON-MACDONALD.—On the 7th ult., at the Parish Church, Northam, S. D. MacVicar, L.R.C.P.Ed., L.R.C.S.Ed., to Ada J., widow of the late W. D. Robertson-MacDonald, of Kinlochmoidart, and daughter of the late Thomas Littledale, of Highfield.

SUTTON—DUNSFORD.—On the 28th ult., at the Parish Church, St. Helier's, Jersey, Alexander Arthur Sutton, L.R.C.P. Ed., L.F.P.S. Glas., Army Medical Staff, to Annie Aubert, eldest surviving daughter of the late Gen. H. F. Dunsford, C.B., Bengal Staff Corps.

DEATHS.

DE CASTRO.—On the 23rd ult., at The Engadine, Torquay, Devon, James Cato De Castro, M.D., F.R.C.S., aged 63.

JEPSON.—On the 23rd ult., at Hampton, Henry Jepson, F.R.C.S., in his 91st year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, December 5.

Lectures
ON
FIBROID DEGENERATION AND ALLIED LESIONS OF THE HEART, AND THEIR ASSOCIATION WITH DISEASE OF THE CORONARY ARTERIES.

BY JOHN LINDSAY STEVEN, M.D.,
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; AND ASSISTANT TO THE LECTURER ON PATHOLOGY IN THE WESTERN INFIRMARY OF GLASGOW.

LECTURE I.

INTRODUCTORY.

THE condition of the heart wall, the consideration of which is to form the main object of the following remarks (viz., a development of what appears to the naked eye to be fibrous tissue in the midst of the muscle substance), is one which most English authorities would probably class under the term "chronic interstitial myocarditis," but which is frequently, though not invariably, to be referred to a cause quite different from that indicated by this term, implying as it does inflammatory action of a chronic kind. This fibrous transformation is most frequently met with in the left ventricle, may not be at all apparent either on the external or internal surface of the cardiac wall, and generally, though not invariably, occurs in association with widespread degenerative changes of the arterial system, obviously involving in most instances the coronary arteries of the heart. Besides the change just referred to, a more acute process of the nature of softening is also frequently met with in association with the same degenerative arterial changes or with embolism; and although the appearances of this acute condition are very different from those of fibrous change, yet the operating cause is so obviously similar that the two must frequently be regarded as different stages of the same affection, or as differing from one another only in degree. The details of the cardiac lesions thus briefly referred to, and of fatty degeneration as associated with arterial disease, will be described in due course, but in the meantime it will be necessary to give some account of our previous knowledge of fibroid disease of the heart.

HISTORICAL AND CRITICAL ACCOUNT.

The conditions of the heart wall (especially fibrous transformation[1]), which form the subject of these lectures, have long been described by special observers, but it is only of recent years that what appears to be, in most instances, their true pathological significance has been hinted at, and that much more on the part of continental than of English physicians. From the time of Morgagni downwards frequent references are to be found in medical literature to a fibrous condition of the heart-wall, apart from the lesions met with in connexion with the valvular apparatus. It is to be noted, however, that in many of the earlier writings reference is made to those conditions only where the fibrous change had advanced so far as to be visible on the surface, without requiring any special dissection of the muscular tissue for its exhibition. Thus Morgagni,[2] in his twenty-seventh letter, which treats of "Sudden Death from a Disorder of the Heart," article 17, after giving illustrations of calcareous plates in the substance of the heart, writes as follows: "For it is certain that the fleshy fibres of the heart themselves sometimes degenerate into a tendinous hardness. Albertini, therefore, saw in some bodies 'that the substance of the heart from the basis to more than half its extent had become tendinous, as it were, both in consistence and colour; which kind of metamorphosis I have it in my power to confirm, if there were any occasion, by an observation of my own.'" It will thus be seen that the condition has been recognised from the earliest days of pathological anatomy, and it is interesting in the light of modern research to observe that the term "degenerate" is used in the description of the change. It is not to be supposed, however, that the term necessarily meant the same to Morgagni that it does to us.

Towards the end of the last and the beginning of the present century medical literature abounds in communications on the subject of aneurysm of the heart, a condition which is very apt to follow upon the morbid condition at present under review. These records are therefore of great interest in the present investigation, and a few of the more important may be shortly referred to. Dr. Matthew Baillie[3] in his work on Morbid Anatomy describes a case of aneurysm of the left ventricle, and refers to the rarity of the condition. He explained the occurrence of the aneurysm by the muscular tissue at the apex being thin and weak, and so unable to resist the impulse of the blood against it. In 1817 Portal[4] published a long article on the subject of cardiac aneurysm, mainly from an etiological point of view. Among the different causes which he states as giving rise to aneurysms of the heart, the following may be mentioned: (1) the formation of false membranes inside and outside of the heart; (2) engorgement of the coronary arteries and veins; and (3) serous and purulent infiltrations. In the second of these it would seem as if we had a hint of the relationship which exists between a diseased condition of the coronary arteries and the development of cardiac aneurysm, but, so far as I can gather, the author simply refers to a dilatation of these vessels as one origin of aneurysm, and not to any nutritive change in the muscular tissue. About the same time important observations were published in France by Breschet[5] and Reynaud.[6]

Another very important paper in connexion with this subject from an historical point of view is that of Mr. John Thurnam on Aneurysm of the Heart.[7] Although, like the others just referred to, not directly bearing on the subject of fibrous transformation of the heart, the essay is very important from the fact that many of the cases were found to be associated with what is called "fibrous degeneration" of the heart-wall. With regard to the causation of the "fibrous degeneration" itself, the views adopted are pericardial adhesions and rheumatic inflammations. But nowhere is there found any allusion to the state of the coronary arteries as an etiological factor, nor are there any references to fibrous change as a morbid state of the heart-wall *sui generis*, and apart from aneurysm. Although in several of the cases the coronary arteries are mentioned as ossified, no opinion is expressed as to the probable relationship of this to the aneurysmal state. Interesting statistics are also given by Thurnam as to the situation of the aneurysm. Out of 74 cases, 58 were situated in some part of the left ventricle; and "the 67 aneurysms which occurred in the 58 cases, omitting one case in which this is not mentioned, may as regards situation be thus distributed: at or near the apex of the ventricle, 27; in different parts of the base, 21; in intermediate portions of the lateral walls, 15; in the interventricular septum, 3. ..... To conclude these observations on the situation of the aneurysms of the left ventricle, the only general conclusion that we can come to appears to be that the thinnest parts of its walls, or the apex and highest part of the base, are those which are much more frequently than any others the seat of the disease." This in general agrees with the observations of more recent writers and also with my own. It will thus be seen that in the record of Thurnam's cases we have a most important contribution to the literature of this subject from a pathological as well as from a historical point of view. In 9 cases the muscular tissue was the seat of more or less extensive "fibro-cellular degeneration," caused by inflammation it was supposed. If the disease was present to such an extent as to cause aneurysm in so many of the cases, we have strong reason for supposing that in its slighter manifestations, which are easily overlooked, it may occur much more frequently. The fibro-cellular degeneration, however,

[1] I use the terms "fibroid degeneration" and "fibrous transformation" as synonymous, and I think the latter is more scientifically correct. It is a real transformation into fibrous tissue with which we have to deal, so that the term "fibroid" seems rather cumbrous.

does not seem to have been regarded by Thurnam himself or by others as an independent morbid state; and one of the objects which I have at present in view is an attempt to establish that in fibrous transformation of the heart wall we have a diseased condition which has as much right, from a clinical as well as from a pathological point of view, to be considered an independent affection of the heart as fatty degeneration, or even as certain valvular lesions.

Another reference in regard to this subject, important from an historical point of view, may be found in the work of Dr. Ramadge on the Heart.[8] In the chapter on Carditis he refers to a condition called "induration of the heart," said to be one of the results of inflammation attacking the muscular or intermuscular cellular tissue. "Sometimes," he adds, "the consistence of the organ is fibrous or tendinous; sometimes cartilaginous." Similar brief references to the condition may be found in most other text-books on heart disease, up till the present time.

Coming now to more recent times, it is found that this condition of the heart-wall has been abundantly observed and described by English physicians and pathologists, although, so far as I can find, the relationship of the change to obstructed coronary circulation has been almost entirely overlooked, and, as a general rule, it has been attributed to chronic myocarditis, probably not without truth, in a certain number of cases. In 1872 the attention of the profession in England was strongly directed to this subject by the Lumleian Lectures of Dr. Richard Quain on the Diseases of the Muscular Walls of the Heart.[9] Under the name "connective tissue hypertrophy," Dr. Quain enters into a full consideration of this affection of the myocardium. No one can read these lectures without seeing that the author was very strongly of opinion that the morbid state originated in an inflammatory action. "The origin," says he, "of the disease is unquestionably to be sought for in a chronic interstitial inflammation or hyperplasia." But he does not seem to recognise any influence on the part of the coronary arteries in bringing about fibrous transformation, although, in describing fatty heart, he points out that "there are no communications between the two coronary arteries; and hence in obstruction of one no collateral circulation can be set up." The strength with which the inflammatory theory is inculcated is further seen in the remarks on treatment: "In connective tissue hypertrophy, if we could diagnose it in its early stage, remedies likely to subdue the inflammatory state in which it takes its origin might have a beneficial influence." Here and there, too, statements which seem to contradict one another are met with, as if, on the whole, the true significance of the condition were not perfectly clear to the mind of the lecturer. Thus: "In connective-tissue hypertrophy the freedom of contraction of the fibres is restrained by the surrounding new tissue, and such a heart is dynamically weak. It would seem, so far as present observation goes, less likely to dilate than the simply degenerated heart"; whereas in the section on aneurysm of the heart he speaks of "the production of a fibroid cirrhotic state which yields to the internal pressure."

During the twenty years which preceded the delivery of Quain's Lumleian Lectures numerous cases of this transformation of the heart wall had been recorded in the current medical literature, to a few of which I may refer in some detail, in order to give some indication of the predominating opinion in the profession concerning the lesion. In 1854 Dr. W. T. Gairdner[10] reported a case of ossification of the coronary arteries, with tendinous degeneration of the heart; and I may add that this is one of the few records that I have been able to consult in which any mention is made of the coronary arteries. In the great majority of cases recorded the state of the coronary arteries is not mentioned, and therefore one is justified in coming to the conclusion that they had not been specially examined. In the Transactions of the Pathological Society of London is contained a rich collection of cases, a full reference to all of which is to be found in Dr. Hilton Fagge's communication, to be immediately referred to. Dr. Bristowe,[11] in recording a case of what is undoubtedly fibrous transformation, states that the cause in all probability was pericardial adhesion, and explains the production of the fibrous material by supposing that a deposit of lymph capable of organisation had been deposited between the fibres, the condition being thus comparable to a cirrhosis. No mention is made of the state of the coronary arteries. Again, Dr. T. Henry Green[12] records a case of sudden death, in which a patchy deposit of fibroid tissue was found in the left ventricle. The aorta and cerebral arteries were atheromatous, but the state of the coronary arteries is not described. The view expressed by Green in his pathology as to the mode of production is that it is secondary to an inflammatory process, commencing either in the peri- or endo-cardium. Interesting cases, from our present point of view, are also recorded by Bence Jones, J. W. Ogle, Whipham, Payne, Wilks, and Moxon.[13] Some of these cases, however, described by the contributors as fibrinous masses in the heart wall, I would regard as examples of the acute process—i.e., of infarction of the heart, which, as I have already indicated, is closely related from an etiological point of view to fibrous change. Moxon, however, in recording a case,[14] regards the fibrinous mass in the heart-wall as coagulated blood, which had been effused into a partial rupture, and he distinctly recognises the state of the diseased coronary artery as a cause of the rupture. With the exception of Dr. Moxon's case, the state of the coronary arteries is not described in those referred to above; and, although the relationship between diseased arteries and localised patches of extreme "fatty" change (as it was considered) in the myocardium had been made abundantly clear by Quain and others, it does not seem (judging from the records) to have struck many of the observers that there was any necessary connexion between arterial disease and the morbid state at present under review.

Without doubt one of the most important monographs on this subject is that of the late Dr. Hilton Fagge on Fibroid Degeneration of the Heart,[15] which may be said to contain the sum of British experience of, and teaching on, this subject up till the year of its publication—1874. The paper contains the results of much labour and thought, and in many places is to be regarded as a forecast of still more modern views on the subject; but a most striking feature is that in the midst of the most cogent reasoning on the pathology of the condition, not a word should have been said as to the etiological significance of obstructed coronary circulation. The first part of the paper gives the record in a very perfect way of eleven cases of the affection, whilst in the latter part the author states his opinions of the pathology of the condition, a few of which may be briefly referred to in order to give an idea of their wide scope. "For it is to be observed," says he, at page 89, "that this affection never attacks the whole heart at once, nor even the whole of a single chamber. It is always more or less localised, and sometimes invades only a very small tract." Such a statement seems to me to be a very strong argument in favour of the circulatory theory of its origin. At page 90 he says, "In the early stage, however, it sometimes seems that a retrograde change in the muscular fibres of the heart advances more rapidly than the growth of the fibrous tissue that should accompany it"; and he goes on to show how a softening, not unlike a pyæmic abscess in appearance, may be produced in some cases. It is very strange that he should have argued in this way, and yet not have suggested any connexion between obstruction of the coronary arteries and the lesion in question. We must, however, regard these statements of Dr. Hilton Fagge as forecasts of the still more modern views and observations of Weigert and Huber on this subject. He goes on to speak of the frequency with which aneurysm is due to this affection, and to point out how rupture of the heart, so frequent in local fatty degeneration of the muscular fibre, very rarely occurs in this condition. I think, however, that this statement must be received with some hesitancy, for, as I pointed out about two years ago in a paper on Rupture of the Heart, there is good reason for believing that many cases are not due to localised fatty change at all, but to infarction. "With regard to the *causes* of fibroid disease of the heart," says he, "we seem to be at present completely in the dark." He discusses in detail the influence of pericarditis, syphilis, &c., and points out that fibroid change of the heart-wall may be a cause of sudden death.

As I have already indicated, the relationship existing between diseased coronary arteries and localised extreme fatty degeneration (leading to rupture in some cases) had

been insisted on by Quain and others many years ago; but to show that the possibility of disturbed coronary circulation setting up other morbid states of the cardiac wall (more nearly allied if one may judge from the descriptions given to the conditions forming the subject matter of the present remarks) was an idea which occurred to one of the greatest living masters of our art in the earlier years of his work, I may here briefly refer to Sir William Jenner's paper on Congestion of the Heart.[16] In this communication, which was made to the Royal Medical and Chirurgical Society of London, he writes: "The principal object of this paper is to call the attention of the Fellows of the Society to the occurrence of congestion of the muscular tissue of the heart; to the most common and direct consequences of that congestion—viz., induration, toughening, and thickening of the walls of the heart; and to the influence which those changes of texture exercise as predisposing causes on the development of permanent dilatation of the heart." The chief interest and importance of this paper are clinical, for it seemed to me, in reading it, that the pathological details were somewhat vague and indefinite, and my main object for referring to it at this point is to show, on the authority of a great clinical observer, the necessity of considering the condition of the coronary circulation in all affections of the heart.

In 1881 a most important paper on Fibroid Degeneration of the Heart was read by Dr. Charlewood Turner at the London meeting of the International Medical Congress.[17] In this paper he gives a minute description of the appearances, naked eye and microscopic, of three cases which he had the opportunity of carefully studying. In this article the influence of obstructed coronary circulation as an etiological factor in the production of fibrous transformation is, so far as I have been able to examine, for the first time categorically mentioned in English medical literature. "Other facts," he says, "suggest the possibility of the origination of localised fibroid degeneration as a result of arterial obstruction, or of venous thrombosis from injury to the vessel from overstraining the walls of the ventricle." And he further shows how some of Dr. Hilton Fagge's cases point to the same thing. From all points of view Dr. Turner's article must be regarded as a most valuable and original contribution to the literature of the subject. In the latter portion of his observations he deals with the generalised form of fibroid degeneration which is met with in dilated hearts, and which may contribute to cardiac failure, but which is a subject beyond the scope of my present investigation.

Having so far dealt, in as complete a manner as has been possible for me, with the work of the more recent English observers, it now becomes necessary that I should give some short account of the foreign literature of this subject which I have been able to consult. In the writings of two German observers—viz., Professor Weigert[18] and Dr. Carl Huber,[19] I have met, for the first time, with what appears to me to be an accurate and tenable explanation of the relationship existing between obstruction of the coronary arteries and the formation of fibrous patches in the walls of the heart, and I do not think I can do better than give a brief abstract of the views expressed by these gentlemen. My friend Professor Weigert, in his observations on the infarction of the heart, has shown that, where the circulation is slowly interfered with by sclerosis of the arteries, atrophy, with destruction of the muscular fibres, takes place without injury to the connective tissue. The shrunken fibres are thus set off by the stringy connective tissue, and this process, he considers, really constitutes the so-called chronic myocarditis. In such cases he has good ground for believing that the vascular change caused the destruction of the muscular fibres as a primary factor. If, however, the arrest of the circulation is more sudden in its onset, then yellow dry masses similar to coagulated fibrine make their appearance. Often the tissue appears quite normal (sometimes the transverse markings being quite apparent), but the muscular fibres and the connective tissue show no nuclei—a necrosis has occurred. Around these masses, as a reactionary phenomenon, abundant round and spindle cells are found.

Weigert's observations, which I have just noticed, appeared in the course of a long paper on the general subject of the Occurrence of Coagulation in the Tissues, and were followed by those of Huber in 1882. In Huber's paper the whole question of the so-called chronic myocarditis is discussed in a broadly scientific spirit, and his facts and conclusions are so convincing that it is difficult, after a careful perusal of the article, to arrive at any other opinion than that the condition of the coronary arteries must be regarded as one of the most important etiological elements in the production of the morbid changes at present under consideration. He bases his opinions on eighteen cases given in the paper, and a number of others which he thought it unnecessary to record, in all of which the fibrous changes associated with distinct vascular disease were well marked; and, in addition, he gives brief details of four or five others, in which the acute affection or infarction of the heart wall was distinctly present. He describes the lesion as the occurrence in the heart-wall of lines or streaks of firm, tendinous, glancing tissue running parallel to the muscular fibres, and somewhat depressed beneath the level of the cut surface of the surrounding muscle. It is mostly observed in the median layers of the cardiac parietes, and is often not to be seen beneath the endocardium or pericardium. This is precisely the condition that I have observed in my own cases. He further remarks that the process, as it presents itself anatomically, is what is most commonly regarded as chronic myocarditis, and that until quite recently syphilis, rheumatism, or inflammation spreading either from the endo- or peri-cardium was regarded as its cause. He then proceeds to show by very cogent reasoning, as it appears to me, that in a very large proportion of cases indeed the lesion must be looked upon as primarily a vascular one. It therefore becomes at once evident that, from a strictly scientific point of view, the terms "chronic myocarditis," "indurative interstitial myocarditis," &c., are, as has been mentioned at the outset, in a large majority of cases misleading.

Since the foregoing remarks were originally penned, the splendid work on Medicine by Dr. Hilton Fagge has appeared, and one cannot help referring to the universal feeling of sorrow experienced by the entire profession when the gifted author was so suddenly called away before seeing the end of his labours. In the article on Fibroid Disease of the Heart,[20] it will be found that Dr. Fagge had fully appreciated the value of Weigert and Huber's researches, and saw in them an explanation of many of his own carefully recorded cases. He refers to myocarditis, syphilis, and thrombi as causes, but obviously places most importance on the relationship existing between fibroid change and disease of the coronary arteries; and, referring to two of his own cases of infarction of the heart, he writes the following sentence: "Thinking over these two cases, I have long seen clearly that the peculiar change in the muscular tissue must be the primary affection, and that the fibroid development must be secondary." He then proceeds to speak of the light thrown upon the condition by the researches of Weigert and Huber.

Ziegler[21] has also very fully described acute necrosis of the heart-wall under the name of "myomylacea cordis," and has clearly related this change to obstructed coronary circulation; and the connexion is also insisted upon by Birch-Hirschfeld[22] in his large work on Pathological Anatomy.

The subject of interstitial myocarditis has also excited considerable attention on the part of French physicians, and in 1880 an account of a case was published by M. Déjérine.[23] In looking through his paper, I find that the case was one of anæmia complicated by aphasia &c.. At the post-mortem, the heart was found to be the seat of interstitial myocarditis, which was also stated to be primitive. As the consequence of the myocarditis, which he supposes to have been due to the anæmia, clots were formed in the cavities of the heart, which explained the occurrence of the aphasia. Holding the opinions which I have already indicated as to the pathology of fibrous transformation of the heart wall, I would rather be inclined to regard the interstitial myocarditis as also the result of embolism, and the description of the morbid appearances is in some places distinctly suggestive of infarction.

Dr. Wickham Legg's Bradshawe Lecture on Cardiac Aneurysm[24] is a most valuable contribution to our medical literature, and one of very considerable importance as regards my present subject, because in discussing the etiology of "fibroid disease" he differs from the views of Huber and Cohnheim. He makes no mention of Weigert's paper on Coagulation Necrosis, in which the theory was first promulgated, and which was published the year before Cohnheim's on the Results of Obstructing the Coronary Arteries of the Heart. His first objection is as to the age of Huber's patients, and he mentions several young persons who had the disease, and in whom the coronary arteries were reported healthy. Now, in going over cases of this disease, I have been struck by the fact that in very many the state of the coronary arteries is not mentioned at all, and unless there be a specific statement, at least in the earlier recorded cases, I think we are justified in concluding they were not specially examined. His next objection is that in a case of Greenfield's the orifices of the arteries were obstructed without producing any result, except generalised molecular fatty change. Now, I am strongly of opinion that a distinction must be drawn between cases where the orifice is obstructed and cases where individual branches are occluded. In the former class of case, I think, resulting fatty degeneration is the rule. His next objection is as to the anastomosis of the cardiac coronary arteries, and this objection I will examine further on. As has been observed, the paper is a most valuable one, and the views of so careful an observer must be thoroughly taken into account, in order to arrive at any conclusion as to the true nature and cause of this interesting disease.

I have thus endeavoured to give some account of the history of our knowledge of fibrous transformation of the heart. In addition to the articles noticed above, several important papers, some of them of great clinical interest, have recently appeared, but space forbids me to do more than simply mention them. Thus we are indebted to O. Rosenbach,[25] E. Leyden,[26] Albert Robin,[27] C. Paul,[28] and others.

In Dr. Byrom Bramwell's large recently published work on Diseases of the Heart, the subject of fibroid degeneration is included in the chapter on chronic myocarditis, "which," he says, "for practical purposes may be considered as synonymous with fibroid degeneration." In the long account of the etiology and pathology of the condition, not a hint is given of the possible direct connexion which this lesion may have with disease of the coronary arteries or obstruction of these vessels. The author points out, however, that long-continued venous engorgement of the heart-wall may have an influence in its production, and this statement is of importance in connexion with Sir William Jenner's paper, to which I have already referred. The absence of any reference to the causal influence of the coronary arteries in so large and valuable a work shows that the true etiology of a large section of such cases has not as yet been fully comprehended. I do not wish to assert that an abnormal condition of the coronary circulation is the cause of all fibroid conditions of the heart. Far from it; but so far as my experience and that of many others go, it is directly responsible for a very large number, in which anything of the nature of an inflammatory course of events cannot come into court. It is also further obvious that to many cases the term "chronic interstitial myocarditis" cannot logically or scientifically be applied. I am decidedly of opinion that the influence of the coronary arteries in producing many of the well-known lesions of the myocardium has not been sufficiently recognised, and if the publication of the present lectures has the effect of directing greater attention to these vessels among English physicians and pathologists my purpose will have been amply fulfilled. In Dr. Bramwell's article on "Aneurysm of the Heart" its association with fibroid change is fully recognised; and in the account of the author's case of rupture of the heart it is pointed out that the branch going to the ruptured area was obstructed. It is therefore somewhat strange that the great importance of the coronary arteries in all affections of the myocardium should not have been more clearly stated and strongly insisted upon.

A CASE OF TYPHLITIS.

BY J. F. W. SILK, M.D. LOND.,
AND
JAMES F. GOODHART, M.D., F.R.C.P.

THE following case of acute inflammation of the vermiform appendix, succeeded by perforation, general peritonitis, and death, seems not unworthy of being placed on record.

Percival T——, aged twenty, a clerk, was first seen on Saturday, Oct. 22nd, at 6 P.M., and found on his back in bed with legs drawn up, face expressive of anxiety and suffering, and complaining of pain and tenderness in his abdomen and inability to pass urine; the pain was obviously of a rhythmical or griping character, and during the paroxysms the face was distorted and the hands pressed to the sides of the abdomen.

The history obtained was as follows: He was an accomplished athlete, but had not attended the gymnasium for some months, till on the evening of Oct. 19th he indulged in a prolonged course of gymnastic exercise, and recalls distinctly a fall on his abdomen across the parallel bars, which was followed by a feeling of sickness and giddiness. He felt a little stiff and sore about the abdominal muscles after his exertions, and as this feeling did not pass off, he took the next evening (20th) a couple of rhubarb pills, which produced a slight watery evacuation the following morning (21st), but did not relieve the pain. On this day the abdominal pain became gradually more intense, and was referred mainly to the hypogastrium; he felt cold and inclined to shiver, and had a frequent desire to micturate, but could not always succeed in passing any urine. There had been no sickness. Early in September he had sought advice on account of some indefinite pain in the right side, but from this he seems to have completely recovered. With this exception he has always enjoyed robust health. His father died at the age of fifty-six of (?) consumption. His mother is gouty and emphysematous.

On examination his abdomen was found to be uniformly, though slightly, distended and tympanitic, more or less tender all over, and especially painful over the hypogastrium. Tongue large, moist, flabby, and coated with a thick creamy fur. Pulse large and bounding. Skin moist. Has passed flatus freely and been somewhat troubled with flatulence. Has passed no urine for the previous twelve hours, but the bladder does not seem distended. Ordered poultices to abdomen, and small quantities of beef-tea, milk, and ice. To take fifteen minims of nepenthe every four hours. In the evening he passed a small quantity of high-coloured urine with difficulty, had some tenesmus, but only passed a small quantity of flocculent fluid.

October 23rd.—Restless last night; slept, but perspired very freely. Abdomen measures thirty-one inches round umbilicus; less tender; coils of intestine can be felt through the abdominal walls. Pulse weaker, but still full. Temperature 101·8°. Has been slightly sick after beef-tea. Much troubled with flatulence and tenesmus. Has micturated once only, but urine not obtainable for examination. Very thirsty. Profuse perspirations continued throughout the day.

24th.—Seen in consultation with Dr. Goodhart. In much the same condition as on previous day, but weaker. Pain is now chiefly referred to the left groin and flank. The abdomen is much distended and tense, although he has not now any of the pinched expression of peritonitis; nor is the abdomen markedly tender on palpation. The intestinal coils are visible, and we were inclined to think that peristalsis was palpable, but of this we were not quite sure. The urine is still passed with difficulty, and contains a trace of albumen. The rectum contains scybala. The heart and lung sounds are normal. Temperature 100°. Pulse 100, full, anything but peritonitic in its characters. He has not been sick for some hours. Tongue flabby, with thick creamy fur; sweating profuse and rather sour. Fifteen grains of salicylate of soda to be added to each dose of medicine. A small enema of warm water returned, bringing with it much flatus, and giving great relief; another given four hours subsequently brought away a few scybala.

25th.—Decidedly worse. Meteorism marked. Sickness very frequent and violent; vomit gradually becoming distinctly stercoraceous. Occasional slight hiccough. Tongue small

Digitized by Google

and dry. Same trouble with urine; catheter drew off only two ounces. Sweating ceased. Pulse small; temperature 99°. He was given a hypodermic injection of morphia (one-third of a grain) at 6 and 10 P.M., and nutrient enemata every third hour, at first with considerable benefit.

26th.—The vomiting and meteorism subsided, but symptoms of collapse, with cold extremities, jactitation, sighing respiration, &c. supervened, and death ensued at 6 P.M.

Examination of abdominal cavity, fourteen hours after death.—A few greatly distended coils of intestine, small and large, filled the abdomen. The whole of the peritoneum was dull and injected—the visceral portion in definite lines, the parietal more irregularly; omentum reduced to a mere shred; coils of intestines slightly adherent to one another through the medium of a glutinous stringy material. These appearances were but slightly marked in the upper portion of the cavity, but increased in intensity from above downwards. In the pelvic cavity the whole of the contained viscera was matted together by means of a layer of tough whitish-grey lymph the thickness of blotting paper. A little thin purulent material of (?) fæcal odour was contained in the pelvis. The appendix vermiformis was of a deep purple colour, in great contrast to the semi-transparent intestines, and slightly distended. About its middle there was a small circular opening with everted sloughing edges, communicating freely with the bowel on the one hand and the general peritoneal cavity on the other, and large enough to admit the tip of the little finger. From the point of contact of this opening in the appendix with the adjacent peritoneum, to which it was very slightly adherent, the inflammation appeared to spread mainly downwards, but also over the whole peritoneal surface. Permission to examine the other viscera could not be obtained; but no signs of tubercle could be made out, nor were the abdominal glands enlarged.

On closer examination the specimen shows a very intense inflammation of the entire appendix. From the orifice of the ulcer, which is situated about the middle of the appendix, the mucous surface is an ashen grey, and sloughy. It is apparently part of this that has given way; the remainder is intensely injected. It contains nothing. The cæcum is healthy, and the ileum also. In the latter the patches are congested, but not swollen; and the colour is, one may suppose, due to the disturbance of circulation owing to the neighbouring severe inflammation.

Remarks by Dr. GOODHART.—This case is quite a common one, but we think it worth recording because it is so instructive in several ways. And first of all in this, that we consider it to traverse, in a way well worth remark, a statement of Dr. Hilton Fagge in his in many respects inimitable work on Medicine. Dr. Fagge writes: "I have indeed a strong conviction that no case in which the disease can be diagnosed as being seated in the cæcum ever terminates fatally if judiciously managed.....Even when typhlitis presents itself clinically under the guise of intestinal obstruction or of diffused acute peritonitis, I believe that it scarcely ever destroys life if judiciously treated." Far be it from us to attempt in any way to minimise the importance of treating these cases by opium, nutrient enemata, or fluid food, and the avoidance of purgatives. Many a case has certainly been killed by the incautious administration of an aperient. But it cannot be too much insisted upon that these cases are excessively treacherous as regards their symptoms. There were times in the course of the illness in this case when the symptoms were not by any means decisively peritonitic; when all vomiting—by the bye, never very urgent until death was imminent—had ceased; when he had a full pulse and thickly furred tongue, as of some acute febrile disorder. Moreover, it will be within the experience of some of us, no doubt, that typhlitis sometimes presents itself under the guise of a severe pyrexia, so that it has been mistaken altogether for typhoid fever. I have seen several such only cleared up at the post-mortem; and were I to write an article on typhlitis, it would certainly be my business to insist that it is a question in a certain proportion of cases whether they die by the febrile disturbance of the inflamed gut or by the collapse of the peritonitis. And it is very important to insist upon this in the present day. If one were to say nothing about the case, and simply to expose the ulcerated appendix that was removed after death to the light of our knowledge of surgery, without doubt it would provoke the remark, "What a pity the abdomen was not opened and the appendix removed," and we have no wish to turn away from that aspect of the case. One should always be on the look out for localising symptoms in these cases which may enable us to attack them surgically; but I am equally sure from a long experience, and this case bears it out, that in a large number it is impossible to come to any sufficiently definite opinion; and it is impossible to suggest so serious an operation as opening the abdomen unless one can be fairly positive. Even when so there will still be some where the febrile disturbance steps in to unsettle the decision, and I am by no means sure that this is solely the consequence of the disease of the appendix or that it would be dissipated by the removal of that viscus. We discussed these points at the bedside of this poor patient, and we neither of us had any doubt that, whatever might be the cause of the peritonitis, there was nothing at that time that precluded recovery—I personally thought things looked most favourable—and nothing in the symptoms that would allow of our entertaining the idea of opening the abdomen. Thus it is with many another case. Now everything looks hopeful, hardly even critical, and an operation has not come within the horizon; a few hours pass by and the patient is moribund, and the sun of surgery for that case has set. And that is the difficulty of practice.

One word may be added concerning the pain in peritonitis: it is an exceedingly treacherous guide to the localisation of the malady. Others have noted that with disease in the region of the cæcum the pain may yet be experienced chiefly in the left groin, and so at one time it was in this case. The early and persistent inability to pass urine is also worthy of remark. It is a symptom of peritonitis that is well known as an occasional occurrence, but in this instance was peculiarly marked, and in conjunction with the pain at one time present on the left side might well have caused a mistaken diagnosis.

ALBUMINURIA IN THE APPARENTLY HEALTHY.

BY ALEX. W. STIRLING, M.D., C.M.

THE following notes are taken from a paper presented as an M.D. graduation thesis to the University of Edinburgh in the beginning of May. In it I considered the cases of albuminuria of the apparently healthy which had already been published, the experiments which had been made and the reasons why few of them were of value, as well as the theories which had been advanced in connexion with the subject; but in the space now at my disposal I am able to introduce only a brief notice of some of the points there discussed more fully.

Table I. will give at a glance the general results of observations made on the occurrence of albuminuria among boys. The greatest care was taken that no error should spoil the results, and at least four different reagents were used to test each specimen of urine, no urine being passed over till I was completely satisfied whether a precipitate were albumen or not. The reagents used were: (1) Heat and acetic acid, which I prefer to any of the others. There is little fear of making the solution too acid in these cases. (2) Nitric acid in the cold. (3) Roberts' brine test, sulphate of magnesia and nitric acid. (4) Picric acid. Also, sometimes, (5) potassium mercuric iodide, and (6) ferrocyanide of potassium. But the first four were used for every urine, and were added by means of pipettes. The boys concerned in this special investigation belong to one of the large training ships on the Thames, and only those in good health were examined. The urine was passed always at 9 A.M., about three hours after rising, at which time albumen will almost certainly be discovered if present at all during the twenty-four hours. It was found in 77 of the 369 boys examined, and I ascertained by several subsequent experiments that, speaking generally, it was not a passing condition, but present at the least for months. The quantities of albumen varied from a slight cloud to one-sixth of the column in the test tube, and in one case—not, however, one of the ship boys—I have seen on several occasions as much as one-half. The urine was generally pale and watery; the specific gravity averaged about 1020; the reaction varied from neutral to strongly acid; deposits, except urates, were rare, though uric acid and oxalates were sometimes present. A considerable number of specimens were examined for tube casts, but with the exception of once or twice, when hyaline casts were doubtfully present, none have been

Digitized by Google

found. It will be observed, on looking at the table, that the effect on boys of blowing instruments is very marked, a fact which had not been pointed out till I wrote the thesis from which these notes are taken, and which Professor Grainger Stewart, since reading my dissertation, has confirmed in a paper read before the Royal Society of Edinburgh. I have attributed this to the effects of backward pressure on the renal vessels. That it is not due to the age of the boys is evident from the fact that the percentage is higher among the band boys at all ages; and that the length of time during which they have been in the band makes a considerable difference is brought out at the age of sixteen, where the total percentage of albuminurics not in the band is, if anything, less than that at fifteen, while of those in the band at sixteen, who had played for about nine months longer than the boys fifteen years old, the percentage with albuminuria is higher than at the latter age by 5·5. Dr. Lauder Brunton has referred the albuminuria of cold bathing to pulmonary spasm, and Dr. Schreiber has shown by experiment that compression of the thorax in young subjects for ninety seconds will cause albuminuria; while Dr. Ralfe, in criticising Leube's experiments on the effect of exercise, says that the weight of the soldier's accoutrements upon the chest may have been a cause in the production of the albuminuria. M. Stichel of Paris has seen blindness produced by the playing of wind instruments—due, he says, to passive cerebral congestion, with a similar condition of the retina and choroid. It is a difficult thing to decide whether or not masturbation may have anything to do with the albuminuria of adolescents. I requested the chief officer to give me the names of some of the boys whom he knew to be guilty of this habit. He sent me thirty-seven, and on comparing them with my list I found that in the urine of fourteen of the number albumen had been found. It may be that the renal vaso-motor centre is weakened by the habit, but that it is not practised by all adolescent albuminurics I am satisfied.

The following is, in a few words, the daily cycle of the albuminuria as I first observed it in 1881, and my experience since has assured me that it is the common one among adolescents. The urine is usually found to be absolutely free from albumen while the patient remains in bed, and it makes its appearance within a variable but generally short time after the assumption of the erect posture, and independently of food and all other conditions. The albumen continues in the urine for, it may be, only an hour or two, or perhaps in varying quantity throughout the day, but as a rule it is disappearing in the afternoon, and is entirely gone by bedtime. It may be made to disappear at any time by merely lying down, and will not occur in the urine throughout the day if the patient keep quiet in bed; though if he rise towards evening, when the albumen is generally absent or scarce, it will be found to be present in quantity larger than is common at that hour, though not always in so great amount as is found under ordinary circumstances in the morning. The ingestion of food has little effect in producing the albumen, and *it is not breakfast which causes the frequency of its appearance in the morning.* Sometimes I have seen a slight rise after a meal, but this is trivial and by no means constant. I had boys brought ashore to the infirmary and confined to bed, and then albumen was absent from the urine till they got up, breakfast or other meals having no effect. I have made very many and various experiments in connexion with this subject, all tending to prove the same thing. One case, not a ship-boy, lived entirely on milk for thirteen months on account of the albuminuria, but that had not the slightest effect in reducing the quantity. The experiments which are said to show that albumen may pass through the urine in a perfectly normal condition of body seem to be insufficient, and it is more probable that there is always some change in the epithelium or blood supply of the kidney, through nervous action or direct irritation, before this is possible. When due to the irritation of crystals, the albumen probably comes from the convoluted tubes, and not from the glomerular epithelium, as it has been said to do. Cases of albuminuria which have been published as due purely to the presence in the blood of a more diffusible albumen formed during digestion show, I think, little evidence of this being the *sole* cause, and are in reality more likely to be dependent upon vascular changes in the kidney peculiar to the period of digestion, to a reflex action on the renal vessels from the digestive canal, or to a deficiency of the barrier power of the epithelium, the result possibly of some previous illness, and so slight as to pass only albumens more than ordinarily diffusible. That there do exist degrees of deficiency in this power of the epithelium is probable from the occurrence of those cases in which the albumen has been found to consist entirely of the more diffusible paraglobulin, or else we must conclude that the apparatus for preventing the passage of paraglobulin is separate from that concerned with serum-albumen. The amount of the urea excreted has no relation to the albumen whatever, the relative amounts of these varying indefinitely, and the actual quantity of urea being usually normal. Exercise, as by walking &c., thoroughly tried in one case, did not have any effect in producing albuminuria, unless complete exhaustion were also produced. When lying in bed in the late morning, when it would certainly have been abundant had he been upright, he worked hard for twenty minutes with a heavy weight without causing the slightest trace to appear. The one thing which does have an intimate relation to the albumen is the rising to the upright position; and so constant has this proved itself that I have proposed the name "postural" for this form of albuminuria. I have also endeavoured to explain its cyclical character in accordance with this fact. The theory of Dr. Pavy, who first applied the term "cyclic" to it, is that it may be compared to the daily variation in the excretion of phosphates in the phosphatic diathesis (which name is sometimes given to a deposit of earthy phosphates, which is not at all uncommon in health and even in acid urines, and which I some years ago ascertained by quantitative analysis not in the least of necessity to indicate an increased excretion of phosphates, even when the fluid has been as white as milk from their presence), and also to the daily rise and fall of the body temperature, neither of which, Dr. Pavy[1] says, have so far been found susceptible of explanation. He therefore concludes that the albuminuria is an illustration of a "physiological cyclic change." The following I wish to offer as another explanation of the periodicity of the condition:—When the individual in question is recumbent, the renal vessels are nearly on a level with the heart, there is no great column of blood to be supported, and this, along with the absolute rest of the sleeping condition, tends to a state of easy circulation through the kidney. The vessels are able to contract gently on the blood, the tendency to congestion which they experience during the day is removed, and by morning they are quite unaccustomed to the necessity of any special effort to keep up a normal state of matters. Then comes the time to rise; the patient jumps from bed, a sudden rush of blood takes place to the kidney, the vessels are thrown into a state of wide dilatation, and they, or perhaps I should rather say the nerves which govern them, receive a shock which they are unable to resist, and for the time being they are more or less paralysed. How long this condition of paresis may last depends partly on their power of recuperation, and partly also on the stress which is afterwards laid upon them. If these are favourable to recovery, we may find the urine cease to be albuminous in a few hours after rising; or if not, it may continue in greater or less quantity throughout the day, increased at intervals by any new stress laid upon it, such as by meals. These, however, may have an opposite effect by stimulating or supplying nourishment to the tissues, as has been exemplified in at least one case. Then sometimes it has been noticed that if a patient be in bed during the day and get up towards evening, the albuminuria has not been so marked as if he had risen on first awaking, probably because the greater excitement of the waking condition and the strength supplied by food had gently accustomed the renal vessels to a state of greater activity without paralysing them, so that they were, so to speak, not surprised on the change of position taking place, and were better prepared for the strain consequent upon it.

I cannot at all agree with Dr. Ralfe that the one cause of this albuminuria is an increased hæmolytic action of the liver, for I have seen no evidence at all to bear that out, nor have I been able to find any fat or metallic-looking spangles such as have been described by Teissier,[2] and which cause him to believe that the pathology of the condition is an over-action of the liver. Neither is a high tension of the arterial system a common feature of these cases, the reverse being more usually found. It is unusual to find the heart enlarged or its impulse accentuated, and the pulse is often soft and yielding. I annex a sphygmo-

SUMMARY.

—	Total number examined.	Total number of albuminurics.	Total percentage of albuminurics.	Average age.	Age varying from—
Ship-boys	369	77	20·8	14½	12 to 16
Workhouse	41*	32	78·0†	50	5 to 94
Cement works	29	6	20·7	31	14 to 66
Ship's officers	11	3	27·3	39	29 to 54
Brewery	11	—	—	28	21 to 36
Totals	461	118	25·6	32½	5 to 94

* Of these 26 were females; average age 34·7, varying from 5 to 94.

† This large percentage is probably due to the numbers of subjects at the extremes of age. It is probable that there is some atrophy of renal structure in the very old, and among the men enlarged prostate may produce some irritation of the urethra which may be sufficient to account for some cases. Many of these cases have been examined three times, and the albumen was present on each occasion.

Digitized by Google

graphic tracing of the most marked case of "functional" albuminuria which I have met with, one in whose urine I have often seen as much as one-half of the column in the test tube to consist of solid albumen. This is a case of a young gentleman now aged twenty-three, whom I have had under observation for six years, and who, though the albuminuria is as marked as ever, has fairly good health, which has not deteriorated during that time. His retina was perfectly healthy, blood in good condition, and his chief trouble was constipation and griping pains in the abdomen, accompanied by a languid state of body. (See sphygmogram.)

Most of my cases have complained of nothing whatever, but have been growing boys; and though the majority of them have had measles, a history of scarlet fever, diphtheria, or the other illnesses usually supposed to be capable of leaving behind them unpleasant traces on the kidney, has not been at all common.

By way of treatment I have used iron, arsenic, strychnia, ergot, arbutin, digitalis, &c., but the beneficial effect of any of them is not sufficiently distinct to be discussed among these notes.

With regard to the advisability of insuring cases of cyclic albuminuria, I have suggested that, in the present state of our knowledge, the most satisfactory method of dealing would be for the companies to accept an apparently healthy albuminuric at a high premium, agreeing however, to rearrange this on their being satisfied of the disappearance of the albumen for such a length of time as would give reasonable expectation of this being permanent.

Lately I have made some further observations, chiefly on older people; and these I give concisely in the form of a table. (See Table II.)

A METHOD OF TREATING POTT'S FRACTURE.

BY E. W. ROUGHTON, M.D. LOND., F.R.C.S.,
ASSISTANT DEMONSTRATOR OF ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL.

IN the condition known as Pott's fracture the displacement which occurs is twofold—viz., (*a*) outwards and (*b*) backwards. The first of these deformities is universally recognised, but the second is often overlooked, I believe, because the ordinary method of putting up this fracture (in back and side splints) hides the displacement backwards whilst the apparatus is on, although it does but little to remedy it, so that when the patient begins to walk he finds that his progression is considerably impeded. An examination of the foot in such a case will show that the heel is much more prominent than it should be, that the concavity of the tendo Achillis is increased, and that the foot, if measured from the anterior margin of the lower end of the tibia to the end of the big toe, is found to be shortened. This appearance is shown in Fig. 1.

The ordinary method of treating Pott's fracture by back and side splints is unsatisfactory, because (*a*) considerable difficulty is found in correcting the outward displacement of the foot, necessitating constant rearrangement of the side splints, and (*b*) the backward displacement is not adequately affected unless so much backward pressure is made on the ankle as to incur the risk of a sore heel. To get over these difficulties Cline placed the limb on an outside splint (known as Cline's splint) and flexed the knee so as to relax the calf muscles. This method answers very well as far as the outward displacement is concerned, but has hardly any effect on the backward one. To remedy the latter I have adopted the following modification of Cline's method. The splint used is an outside splint with a foot-piece (Fig. 2), *padded thickest where the foot-piece joins the other portion of the splint.* Three bandages (made of a double fold of Domett bandage) are fixed by means of safety-pins at the points A, B, and C, and placed in the position indicated in the figure. The injured limb, having the knee flexed, is then laid upon the splint so that the outer edge of the foot is well supported by the thick padding before mentioned, and fixed by the bandages in the manner shown in Figs. 3 and 4. Bandage A is first applied; it passes backwards between the limb and the splint, then turns forwards around the back of the limb and makes traction forwards. This is fixed, and then bandages B and C are drawn tight at the same time. Bandage B passes forwards between the splint and the limb, then turns over the front of the leg and pulls backwards.

FIG. 1. FIG. 2.

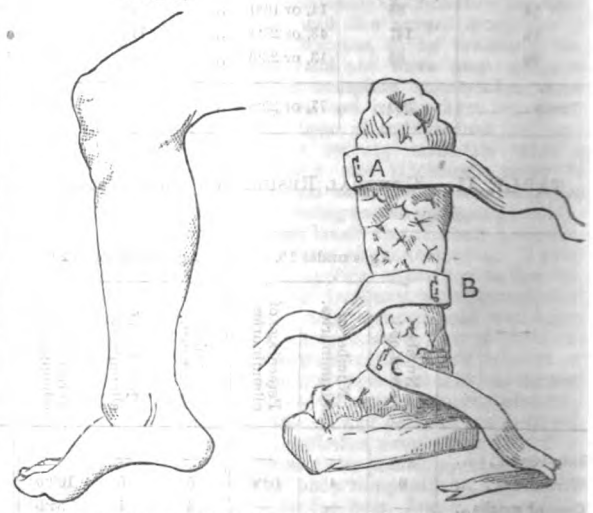

FIG. 1.—Showing the backward displacement of the heel in Pott's fracture.
FIG. 2.—Showing splint with the bandages attached. C is the "heel bandage."

Bandage C (which is the important one) passes from before backwards, between the splint and the limb, *turns over the point of the heel*, and pulls forwards and downwards. Bandages B and C are then fixed by taking another turn around the limb and splint, and fastened with safety-pins (Fig. 4). If necessary, an evaporating lotion may be applied over the inner ankle, which is left uncovered by bandage. Usually in forty-eight hours the heel bandage requires to be tightened, owing to relaxation of muscular spasm. When

FIG. 3. FIG. 4.

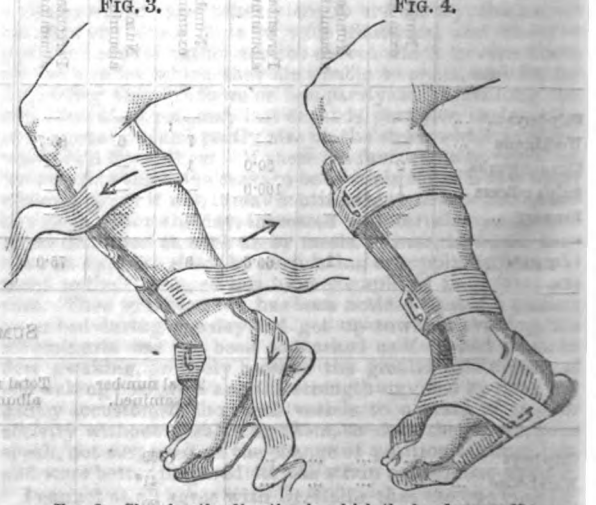

FIG. 3.—Showing the direction in which the bandages pull.
FIG. 4.—Showing the limb fastened on the splint.

the bruising has subsided and sufficient union has taken place, this apparatus is removed and the limb put up in a "silicate" splint, taking care to keep the foot well inverted and at right angles to the leg. After the removal of the silicate splint the ankle may be found somewhat stiff, but this condition may be remedied by manipulation under an anæsthetic.

I have found this method of treating Pott's fracture very

Digitized by Google

simple and efficient, the foot and ankle eventually being as useful and shapely as before the accident. The great advantage of the "heel bandage" is that it exerts uniform and slightly elastic pressure in the direction required, and never produces that unfortunate result—a sore heel.

PERSISTENT HIGH TEMPERATURE IN A BOY, DEPENDENT UPON SUPPURATION WITHIN THE TYMPANUM (?)

BY WILLIAM H. DAY, M.D.,
PHYSICIAN TO THE SAMARITAN HOSPITAL FOR WOMEN AND CHILDREN.

A. C. W——, aged nine, was admitted into the Samaritan Hospital under my care on March 23rd, 1887. He was a highly nervous and sensitive boy, with thick lips, pasty face, expanded nostrils, and light hair. The parents and five other children of the family are healthy.

History.—Three weeks before admission he is said to have fallen in the street whilst running, and to have struck himself on the left temple. It is reported that he was picked up in a state of insensibility and carried into a shop. From that time to the present he has not been to school or into the playground. His mother states that after the accident he became very drowsy, sleeping nearly the whole day in a chair, but apparently not ill. He has had headache for a week, and giddiness and "wandering" up to the present. One day at home he was sick and ill, his mother thinking he might be going to suffer from some fever. A week before he fell he was knocked down by a boy and kicked in the groin and stomach. For some days after he complained of pain on micturition.

State on admission.—He complains of pain in the left hip and over the great trochanter, which is tender on pressure, but there is no obvious swelling or heat, and he can flex and extend the limb without pain. He is indisposed to answer any question, being very drowsy, though quite sensible and intelligent. He also complains of headache, and will not expose his face to the light, but hides it under the bedclothes. The abdomen is natural; the tongue is clean; the bowels are costive. There is a good deal of cough, but the physical signs are only those of slight bronchial irritation; no dulness can be detected in any part of the chest; the heart's sounds are normal. Temperature 104°; pulse 100; respiration 36. The urine is of a dark sherry colour, acid, non-albuminous, sp. gr. 1026. A soap-and-water enema was used, which brought away a copious scybalous dark motion. After this, the skin being dry and dirty, he was put into a warm bath. A mixture containing salicylate of soda and solution of acetate of ammonia was given every four hours. He was supplied freely with milk and beef-tea. At 9 P.M. the temperature rose to 104·4°; pulse 124; respiration 36. No complaint was made of any kind.

On March 24th it was reported that he had passed a quiet night, and did not seem quite so drowsy. The morning temperature was 103·6°, the evening 102·6°. On the 25th a grain of calomel was given, followed by an enema, which produced a copious and light-coloured motion. The temperature at 8 A.M. was 101°; pulse 104; respiration 36. At 1 P.M. the temperature rose to 104°. At 5 P.M. he asked for bread-and-butter and a picture-book, but he soon grew tired and relapsed into sleep. There was no pain, vomiting, or thirst. Five grains of antipyrin were ordered every four hours. At 12 P.M. the temperature was 103·4°. On the 26th, at 6 A.M., the temperature was 103°, when five grains of antipyrin were given, and in two hours it fell to 101·4°; throughout the day it did not exceed 102·6°. The boy enjoyed looking over books, and the only noticeable symptom was undue disposition to sleep. The temperature during the following day varied between 102° and 103·4°, and he invariably roused himself from his drowsy condition after being sponged with cold water. The same physical signs of bronchial irritation were present. The antipyrin was omitted. On the 28th the bowels freely acted. At 3.30 P.M., when the temperature reached 103·4°, he was put into a bath at 90°, which was gradually cooled down to 70° by the addition of cold water. He remained in the bath seven minutes, and when removed to bed, between blankets, the temperature was lowered to 98·6°. At 7.15 it rose again to 103°, when he had another bath. At 7.40 it was 100°; and at 12 P.M. it had risen to 101°. On the following day (29th), at 9.40 A.M., the temperature being 103°, he had another bath for five minutes, when it fell to normal. At 1 P.M. the temperature rose to 104°, and again he had a bath for five minutes, when it fell to 101°, and he became rather livid about the face and hands. At 3.30 the temperature was 103°, and he had a renewal of the bath for five minutes. Ten minutes afterwards the temperature was 98·6°. At 5 P.M. it rose to 103°, and the bath was repeated with like effect. At 7 P.M. the temperature rose again to 104°, and he had another bath. The patient has never had any distinct delirium, and complains now of no pain anywhere. He enjoys his food, but is very pale. When the temperature rises there is no change in his general condition. The morning and evening temperature was 102°; the pulse was regular and good; urine dark sherry colour, acid, sp. gr. 1024, non-albuminous. Cold sponging of the face, body, and extremities was performed three times a day. On the 30th, the temperature being 103° at midday, he was placed in a bath for five minutes. Two grains of quinine were given. At 5.30 the temperature was 104°, but after being in a bath for five minutes he became rather livid and his feet were cold. The temperature was 102°. At 8 P.M. the temperature ran up to 104°, when he had a final bath for seven minutes, the mercury falling to 100°. Pulse 88. The quinine was repeated. On the 31st he complained of pain at the lower part of the sacrum, and was fearfully alarmed at any attempt being made to examine it, his leg being instantly drawn up, and even the weight of the bed-clothes being insupportable. Throughout the day the temperature remained at 103°, notwithstanding cold sponging and quinine. On April 1st he seemed equally distressed, shrieking out and complaining of pain in his hip and sacral region. He was terror-stricken when local examination was attempted. At 1 P.M. the temperature was 105°. The boy admitted later in the day, when seen by myself and Mr. Marmaduke Sheild, that if it were not for the pain in "the back" he should be well, and with a little encouragement he was persuaded to get up and run about the ward. A careful examination was at this time made for disease of the hip or pelvic bones, or caries of the spine, but none of these conditions were detected. In the morning of April 2nd he appeared unable to move, but when his tea was brought to him he sprang up and took it greedily. The highest temperature during the day had been 101°; he had coughed slightly. No remedies seemed to control the temperature for any length of time. On the 3rd, in the early morning, his temperature was 100°, but at 2 P.M. it ran up to 104·6°; notwithstanding this, he took his food well and remained remarkably quiet. On examining the chest no dulness could be detected, but loud rhonchi and cooing sounds were universal over both lungs; the cough was now loose and more frequent. He had greatly wasted since admission, but for the last two days there had been sudden and considerable discharge from the right ear, with deafness. On the 6th the highest temperature was 99·6° and the pulse 84. He was ordered a grain of quinine in hydrobromic acid, and liquor strychnia three times a day. Two days later the temperature ran up to 101°, but he sat up in bed and enjoyed his food, and seemed as well with a high as with a low temperature. On the 11th, the temperature being 101° and the pulse 80, I ordered him meat once a day, and for the next five days the morning temperature was normal, the highest evening being 100°. On the 16th his temperature was normal, he slept less, and talked and played with the other children. He rarely coughed, and his chest was perfectly free from bronchial sounds. The appetite was voracious. For the next seven days his temperature was normal both morning and evening. On the 24th visitors came to see him, and the temperature soon afterwards ran up to 104°; he complained of headache, but seemed well, and relished his food. His medicine was omitted, but resumed again on the 28th. The temperature vacillated between 101° and 103° till May 5th, when it became normal. The urine was of a deep sherry colour; sp. gr., 1026; slightly acid, non-albuminous. As a rule, he slept from 7 P.M. till 7 A.M. without moving, and also generally five hours during the day; so that on an average he slept seventeen hours out of the twenty-four. On May 10th the boy got up, and neither morning nor evening did the temperature exceed 98·4°. He had gained flesh, and during the past week colour had returned to his face, and his drowsy condition had disappeared. He was discharged on June 8th. On July 30th

Digitized by Google

he was reported well, and had suffered no return of febrile symptoms.

Remarks.—This is an unusual, and in some respects a remarkable, case. Although I have met with several instances of unaccountable pyrexia in adults, and especially in children, I have no record or remembrance of any case resembling in its features the one under consideration. Were the symptoms due to some alteration or disturbance in the nervous centres originating in the fall on the head? Were they dependent upon suppuration in the middle ear, or on some undetected condition of disturbance of the digestive system? There is much to recommend the first view. The boy was of a nervous and excitable temperament, and his condition on several occasions closely approached that of "hysteria" in the opposite sex. Moreover, the extraordinary variations in the temperature were suggestive of a neurotic origin. So, too, there were none of the constitutional signs of fever that would have necessarily accompanied a pyrexia of this kind if dependent on the usual causes. The drowsy and lethargic state has often been noted in neurotic individuals, in some cases leading to trance, or the nine days' wonder of a sleeping girl. Yet we have to recollect, on the other hand, that deeply seated collections of matter are often only signified by curious variations in temperature, and that excessive drowsiness with fever is often symptomatic of ear mischief. The rapid improvement of the boy after the discharge of pus would lend some colour to this view of the case. For the first few days I was inclined to think that pulmonary tubercle might be the slumbering element of mischief in this case, as evidenced by the protracted bronchial irritation. But when this had passed off, and there were no special signs of tuberculosis, it appeared to me improbable. The true import of such a high temperature was indeed doubtful. And in this, as in all such cases, I thought it wise to exercise vigilant supervision, and enjoin the strictest rest of mind and body. A remarkable feature in the case was the tendency to drowsiness and torpor. This was an early and constant symptom, and pointed to some important change in the nervous centres. Throughout the illness there was great lethargy, and during much of the time profound stupor, from which he could not be always roused. He generally lay on his left side, with calm features, and when asleep he had quiet respiration and slow pulse. It seemed whilst this drowsy state continued that he might pass into a comatose condition and die. Such a termination seemed not improbable if the patient was not roused to take nourishment. Pyrexia occurring without the general symptoms of fever is especially likely to occur from slight causes in neurotic individuals. It is quite likely that the true explanation of this case hinges on this observation. A delicate and sensitive lad gets the sequence of events not uncommonly noticed. A blow on the head, some suppuration about the tympanic cavity, possibly old mischief lighted up into fresh activity, and a curious train of febrile and head symptoms supervene. In an older person, or a lad of more stolid temperament, the symptoms would probably have been less complicated; but the case affords a striking instance of the readiness with which the temperature of a boy may undergo curious variations, and the great difficulty we often have in practice to trace such complications to their true origin.

ANTIPYRIN AS AN ANODYNE.

By OSCAR JENNINGS, M.D.

THE remarkable effect of antipyrin in the treatment of pain attracting general attention at present, the following cases may be of interest to the readers of THE LANCET.

1. A middle-aged lady with slight ataxic symptoms, including loss of knee jerk, whose chief trouble consisted of intermitting darting pains in the thighs and legs, and constant burning pains in the heels. She was supposed by consultants to have an arthritic affection of the sheath of the cord. Iodide, quinine, colchicum, salicylates, and electricity in various forms, had been all used without success. Antipyrin proved entirely useless, but the patient was slightly improved by a season at Lamalou.

2. A stout middle-aged female medical attendant, a large [illegible], and unable to get any exercise except in a carriage with her employer, was suffering from subacute gout in the feet. She took four grammes of antipyrin daily for a week without any marked improvement, recovery being slow, and probably independent of the medicine.

3. A stout man, thirty years of age, head waiter in a Paris restaurant, suffering from acute gout, was relieved by the same doses in twenty-four hours.

4. An unmarried middle-aged lady, crippled by double sciatica, which obliges her to use two sticks to get about, and who suffers more or less constantly from pain, had tried everything that could be suggested. She tried antipyrin, and it was unsuccessful.

5. A gentleman, aged sixty-nine, was sent to me for a painful affection about the shoulder, which had resisted all kinds of treatment directed by the most eminent neurologists in America. The malady had been variously described as neuralgia, neuritis, and myositis. The symptoms consisted of periodical paroxysms of pain, recurring at night, with inability to move the arms upwards and backwards (to brush the hair, for instance) without causing painful spasm in the muscle. There was also a dull, fixed pain in the right side, and hypochondriasis. Professor Ball, who had recommended the patient to place himself under my care for an electrical treatment, prescribed iodide of potassium and euonymin, by which the pain in the side was permanently relieved. The improvement about the shoulder joint, however, was slow, and the patient, who had expected to be entirely cured by electricity in a month, was becoming discouraged. Professor Sée's communication appearing at this juncture, it was decided to give antipyrin a trial. At first it had but little effect, but after a few days' administration by the mouth hypodermic injections were used instead, with a satisfactory result. The patient, if not cured, recognised that he was greatly improved in every respect – a statement endorsed more strongly by all his friends.

6. A washerwoman, aged forty-nine, was attending at the clinique of St. Anne with precisely the same symptoms, and, besides limitation of the movements upwards and backwards by pain, there was considerable wasting of the muscles. Faradic electricity had been employed for six weeks with the best effect; the paroxysms of pain were relieved, movement improved, and the volume of the muscles restored. The patient, although at considerable inconvenience to herself, never failed to attend the electrical room for treatment. There remained, however, a dull pain, to which she was so accustomed that it was no longer a subject of complaint, and was only mentioned when she was interrogated upon this point. Encouraged by my experience in the preceding case, I again tried antipyrin hypodermically, with an excellent result. The patient now takes one gramme per day and is free from pain, any movement being possible without uneasiness.

7. Antipyrin being said to relieve pain by lessening the perceptibility of the nervous centres, I thought it might be worth a trial in the morphia craving. I gave it in one case which has been already mentioned in the columns of THE LANCET, but the result was not encouraging. The patient stated that it made the craving worse. This, however, may have been a wilful representation for the sake of obtaining a little more morphia. He said, moreover, that he felt sick and giddy, and, as a matter of fact, he did not look well.

8. Upon the same theoretical grounds I gave antipyrin in one case of sea-sickness with good effect.

9. The most striking benefit I have seen following the use of this drug was in the following case:—An American gentleman, an artist, had been overtaxing both body and brain for some time in order to get a picture finished. He had been working in a cold *atelier*, taking meals irregularly, and was morbidly anxious as to success. He had already lost appetite and become sleepless and restless, when he was seized with violent abdominal pains, accompanied by frequent stools containing blood, cerebral excitement, and subdelirium, with fear of impending death or insanity. He was the more excited when I saw him inasmuch as he had been anxiously waiting for an English doctor the whole afternoon, and was just then threatened with a visitation from no less than three. A colleague who arrived shortly after myself suggested the possibility of typhoid, but, as the management of the case devolved upon me, I accepted the diagnosis of the family, which was visceral rheumatism, ordered a morphia suppository and a mixture containing chloral and bromide to allay the symptoms depending upon the brain. The next day the pain was still severe, although the mental excitement was lessened, and

Digitized by Google

the patient begged for a hypodermic injection of morphia, which, he said had been used with benefit upon a previous occasion. This I gave, and was called upon to repeat the dose in the evening. The next morning morphia was again demanded and given, and as I had resolved not to make any more hypodermic injections, I told the patient I could give him no more morphia except in the form of suppositories, and prescribed antipyrin, to be taken in fifteen-grain doses every four hours. The administration was commenced under the influence of the last hypodermic injection, and the pain never returned, the patient rapidly convalescing and leaving Paris shortly after for the United States.

10. I have given antipyrin in one case of zona. The pain disappeared after the third dose of fifteen grains "like a charm," to use the patient's own expression.

11. Of two cases of inflamed painful sore-throat of rheumatic origin, one was greatly relieved.

12. In migraine there can be no doubt as to the efficacy of antipyrin for a time, although, in my opinion, the dose requires to be larger than those mentioned by some correspondents of THE LANCET—fifteen grains at least. I am afraid, however, that the effect will often be found to wear off after a time, or that it will be necessary to increase the dose to an imprudent extent. I know a lady who has been taking antipyrin for migraine for two months, and who already finds that it has lost most of its "magic," although it still procures some relief. M. Norström tells me he has had similar experience.

To sum up. If antipyrin is not an unfailing specific, I have certainly seen it allay pain as speedily and more radically than a hypodermic injection of morphia. Whether any evil results are likely to follow its prolonged use remains, of course, to be seen. There is a good deal of talk at present about the possibility of benzine poisoning resulting from the admixture of this substance with the drug, owing to imperfect preparation, but I must confess that every solution I have used hypodermically has smelt of benzine, and until the end of September, when I purchased an inodorous sample in London, I was under the impression that this was always the case. Like others I have frequently seen giddiness, vertigo, and nausea follow the administration of antipyrin, and ecchymoses and induration at the seat of injection. In one instance where I had associated it with cocaine, according to a formula much used in Paris, the patient felt prostrate and miserable for four or five days. This has never occurred with antipyrin alone.

Paris.

ANTIPYRIN IN THE TREATMENT OF MIGRAINE.

BY W. H. RUSSELL FORSBROOK, M.B. LOND.

So far as I know, the treatment of this troublesome and frequent disease by antipyrin has not been tried in this country. I was induced to try it in the first instance after having read an account of the drug in THE LANCET, written by a German physician, who had given it with success in this and various neuralgias; and I have now myself prescribed it in some hundred cases with an almost magical result. The causes and symptoms of migraine are well known, but its pathology is not so clear, and its treatment by the numerous remedies hitherto recommended has effected little or nothing, in the majority of cases, in shortening an attack. I think, therefore, the misery, depression, and extreme feeling of illness it causes while it lasts, and the almost immediate relief from all this, are a sufficient excuse for venturing to write a short account of my experience of its treatment by this drug.

I have found antipyrin given in fifteen-grain doses every twenty minutes three times consecutively almost invariably removes the pain, depression, drowsiness, nausea, &c., so that in forty minutes, frequently even after one dose, patients express themselves quite well. A single dose, if given during the premonitory signs, will often ward off an attack. Sometimes I recommend another dose in four hours, but not often, as I find the very few cases in which there has not been absolute removal of pain after the third dose, but only partial relief, are seldom further affected. These few cases, however, which are not amenable to the speedy action of the medicine, seem to have the duration of the attack much shortened. One important fact is noticeable, that the period between the attacks has seemed to me to be prolonged; also that succeeding attacks have not been so severe after its administration. The pulse, which is generally slowed during an attack of migraine, appears in some cases to be rendered fuller and quicker. Antipyrin, when given to young women for migraine, sometimes produces a species of intoxication, so that it is as well to be on one's guard; although, so far as my limited experience goes, the only result has been the almost certain and immediate relief from the peculiar pain &c.

According to one theory of its pathology—that of Dr. Liveing,—migraine has a close pathological relation to epilepsy; although one disease is said never to pass into the other. Dr. Liveing thinks that the immediate antecedent of the attack is a state of unstable equilibrium and gradually accumulating tension in the parts of the nervous system especially involved, the paroxysm being somewhat similar to a storm. He considers the seat of the disease to be the optic thalami and the parts between those bodies and the roots of the vagi. Thinking of this close relationship between the two diseases, I commenced to give antipyrin in the headache following an epileptic seizure, and I was glad to find that it acted quite as well as in ordinary migraine in six out of seven cases. I have also prescribed it, following out the analogy, in those cases of epilepsy indicated by premonitory symptoms, or by the so-called aura epileptica, and in the only two cases in which I have tried it I certainly believe that it prevented an attack in one of them; but naturally the drug requires a much more lengthy and searching trial with respect to the headache following an attack of epilepsy, and especially as to its power in the prevention of an attack preceded by an aura, and I merely throw out these hints in the hope that someone with extensive practice in epilepsy will experiment. I have most certainly proved the great value of antipyrin in migraine in my own practice, and I ask others to prescribe it in order to be convinced of its specific action.

Buckingham-palace-road, S.W.

MERCURIC BINIODIDE GAUZE:

A NEW ANTISEPTIC DRESSING.

BY J. C. VOIGT, M.D. EDIN.,
LATE SENIOR RESIDENT MEDICAL OFFICER, BURY INFIRMARY.

SINCE Jan. 1st, 1886, I have used a gauze prepared in the following way. Plain absorbent gauze is steeped in a 1 in 500 solution of mercuric biniodide in iodide of potassium and glycerine: Hydrarg. iod. rubr., 1 dr.; pot. iod., 3 dr.; glycerine, 4 oz.; aqua ad 80 oz. After being well soaked in this solution, the gauze is squeezed out and hung to dry in a darkened room. For irrigation of wounds and washing out of abscess cavities I employ a stock solution of hydrarg. iod. rubr., 2 dr.; pot. iod. 4 dr.; glycerine, 12 oz.; aqua ad 80 oz. This is diluted (with water) from four to eight times before being used. The solutions thus diluted are substitutes for the 1 in 1000 and 1 in 2000 corrosive sublimate solutions. For the dressing of ulcers much weaker solutions—1 in 20,000 and 1 in 40,000—have been employed. The following cases are given as illustrations of the foregoing:—

1. *Right-sided empyema.*—Lilias A——, aged eight years. Empyema opened Jan. 15th 1886. Cavity syringed out with 1 in 10,000 biniodide solution, and drainage tubes inserted. Washed out daily with the solution (diluted to 1 in 20,000 after the third day) and tubes shortened. Drainage tubes removed in three weeks. Patient discharged cured.

2. *Deep cellular inflammation and suppuration under the scalp (after a blow on the head).*—Nancy H——, aged forty-one. Treatment commenced on Feb. 3rd, 1886. High evening temperatures and rigors. Suppuration, involving nearly half the scalp. Free incision and drainage. Syringing with the 1 in 1000 biniodide solution, and dressing with biniodide gauze. Cured by Feb. 15th.

3. Thomas R——, aged thirty-seven. Similar case to the above (after wound of scalp). Here the biniodide solution was substituted for the corrosive sublimate on the third day of treatment, after drainage-tubes had been inserted and counter-openings made. The amount of discharge was noted as being "much less" at the following dressing. The drainage tubes were gradually shortened, and the patient was discharged cured in twelve days.

4. *Large axillary and subclavicular abscess.*—R. W——, aged forty-four. Drainage tubes inserted (after free incision) into axilla, and under pectoralis major. Abscess cavity

Digitized by Google

syringed out with biniodide solution, and biniodide gauze dressings applied. Patientdis charged cured in fourteen days.

5. *Suppurating bursæ patellæ.* (Three cases.)—Free incision, with mercuric biniodide irrigation and dressings of biniodide gauze, followed by iodoform and iodol ointments.

6. *Deep abscess of thigh with suppurating bursa patellæ.*—William C——, aged thirty-six, fell and injured his knee on Nov. 5th, and, when seen on Nov. 7th, the bursa patellæ was found enlarged and inflamed, there was considerable swelling round the knee-joint, and the lower and outer part of the thigh was tender to the touch and swollen. When fluctuation could be distinctly made out, an incision four inches long was made along the outer aspect of the lower part of the thigh. A considerable quantity of pus escaped. The bone was found healthy. The abscess cavity, after being well washed out with the 1 in 1000 solution, was drained and dressed with biniodide gauze. The suppurating patellar bursa was also freely opened and drained. The patient was discharged cured in ten days.

7. *Exploratory incisions, elbow, hip, and knee joints.*—Jas. N—— and Wm. L——, aged forty-one and twenty-five respectively. Extensive suppuration round elbow joint, as a result of injury. Free incision along the posterior aspect of the joint. Olecranon process found denuded of periosteum. Pus evacuated and sinuses laid open. Wounds syringed out daily and packed with biniodide gauze. Both cases discharged cured, with partially movable joints, after a couple of weeks' treatment.

8. *Morbus coxæ.*—Albert O——, aged four, seen in February, 1887. A large bulging abscess found surrounding the hip joint. Exploratory incision (under mercuric biniodide irrigation) along posterior aspect of trochanter. Head of femur found in position in acetabulum. More than a pint of thick pus escaped from the abscess cavity, which extended downwards to about the middle of the thigh and upwards under the gluteal muscles. Long, large-sized drainage tubes inserted; biniodide dressings and extension apparatus applied. Abscess cavity syringed out daily, and tubes gradually shortened until removed altogether. Discharged cured on April 5th.

9. *Suppurating knee joint.*—Henry W——, aged eleven. Joint laid open and drained. Irrigation by mercuric biniodide solution. After two months' treatment, joint found anchylosed and wounds healed.

Summary.—As compared with corrosive sublimate, I find that the biniodide dressings give (1) just as efficient antisepsis, (2) less risk of toxic constitutional effects, and (3) less irritation of the parts surrounding the wound.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

LONDON HOSPITAL.

PRIMARY CANCER OF FEMALE BLADDER; OVARIAN CYSTOMATA; GROWTH REMOVED BY VAGINAL CYSTOTOMY; FRESH GROWTH AGAIN REMOVED BY A SECOND OPERATION; RECURRENCE; SECONDARY GROWTHS IN OTHER ORGANS; THIRD OPERATION; DEATH.

(Under the care of Dr. HERMAN.)

THE following is interesting as the complete history of a vesical tumour. The symptoms produced by the presence of the growth were spread over a long period, and this, with the appearance of the tumour, made it probable at the time of the first operation that it was of innocent character. The report of the microscopic examination was, however, in favour of malignancy, and the repeated recurrences and general dissemination of the disease proved this to be correct. The following notes are by Messrs. Pugh, Lubbock, and Lys, clinical clerks.

S. W——, aged fifty-nine, was admitted into the Victor ward on July 8th, 1885. The patient came to the hospital complaining of passing blood with her urine, of vomiting, and of swelling of the abdomen and legs. She did not know of any relative having suffered from cancer or from any disease resembling it, nor from phthisis. Both parents long lived. She had always lived in the country till the last eight months. Had always been strong and healthy till the present illness. Had all her life worked hard. She first menstruated at thirteen; the flow used to last four or five days, was moderate in quantity, but accompanied with severe pain, beginning two or three days before the flow, relieved on the appearance of the flow, and ceasing on the second day of the flow. She was married at eighteen, but never became pregnant. Menstruation ceased at thirty-four. Her bladder troubles dated from six or seven years back. Then she began to have to strain a good deal in micturition, and her urine was of a deep yellow colour, staining her clothes when it dropped upon them. Two years after this the urine became of a much deeper colour, began to contain small lumps, which she believed to be clots, and there was a sediment after the urine had stood. She could feel the passage of these clots, as they sometimes caused temporary stoppage of the flow of urine. Ever since then she had been passing blood at variable intervals; sometimes she would go as long as eight or nine weeks without passing any, sometimes not so long. The last severe attack was nine weeks ago, when she passed a large quantity of blood, making her feel very weak. Very little has been passed since. About a year ago the abdomen began to swell, and this has especially increased during the last nine weeks. The swelling of the legs began after the last severe attack of hæmaturia. Patient has been losing flesh for some months.

On admission the patient was pale and anæmic, but not much emaciated. Appetite bad; bowels confined. The abdomen was distended by a rounded, firm, elastic, fluctuating swelling; it was dull in front up to five inches above the umbilicus, resonant in the flanks. The circumference at the umbilicus was forty-two inches. Per vaginam, the cervix uteri was found to be healthy; a large solid lump was felt to the left and in front of the cervix. The urine drawn off with the catheter was dark, smoky, neutral in reaction, and contained blood and pus.

July 14th.—The patient having been anæsthetised, an incision was made from the vagina in the middle line through the base of the bladder. Growing from the mucous membrane of the base of the bladder to the left of the middle line was a mushroom-shaped growth. This was grasped with forceps and torn away. The fragments when put together formed a mass as big as a Tangerine orange. The base of the bladder did not seem more fixed than usual to surrounding parts, but owing to the elevation of the uterus (which was pulled up by the abdominal tumour) it could not be pulled down as usual, which made manipulation somewhat more difficult. Hæmorrhage was stopped by syringing with hot water. The incision was left open.

21st.—All pain has ceased. No trace of blood in urine.

31st.—Urine tinged with blood.

Aug. 28th.—Patient anæsthetised; cervix uteri dilated; interior of uterus examined, and found to be healthy. The edges of the wound in the bladder were pared and united by stitches in the usual way.

Sept. 5th.—Stitches removed, opening closed.

25th.—Circumference at umbilicus forty-one inches.

Oct. 9th.—A little blood and pus in urine; no pain. The lump formerly felt through the vagina at the base of the bladder is not now perceptible.

13th.—Discharged.

Mr. Jonathan Hutchinson, jun. (surgical registrar to the hospital), was kind enough to examine the fragments of growth removed. He reports as follows: "The growth was soft, and formed of a very great number of villous processes, so that it was difficult to obtain an extensive section. The processes, however, throughout were of similar structure—vascular fibrous projections covered with columnar epithelium (non-ciliated). Some were broad and short, the greater number of marked tenuity. From the latter the epithelial covering dropped off with great ease. Sometimes one long process appeared to join another. There was considerable round-cell infiltration of the thicker processes, as also of the base from which they grew. In addition to this (forming the most important feature of the tumour) were oval loculi filled with cells which could only be of epithelial origin. This so strongly suggests a tendency to infiltrate that the growth must be regarded as in all probability malignant."

Digitized by Google

The patient was readmitted on Jan. 15th, 1886. The urine now again contained much blood, and the patient was more anæmic. The circumference at the umbilicus was forty inches.

On the 19th the patient was put under ether, and the bladder opened from the vagina by a median incision, as before. The finger, introduced through the opening, felt a mass growing from the upper and posterior part of the bladder. This was grasped with forceps and torn away. Just as the growth had been removed, the patient's pulse and breathing stopped. The anæsthetic was withdrawn and a hypodermic injection of half a drachm of ether given. The tongue was pulled forward and an artificial respiration performed, and after this had been done the pulse and respiration returned. The wound was left open. The next day the pulse was small and the breathing hurried. There was no pyrexia.

Feb. 6th.—Edges of opening pared and united by sutures.

14th.—Sutures removed. Patient can retain urine.

March 19th.—Abdomen measures forty-one inches in circumference. Urine free from blood or pus.

27th.—Discharged.

The patient was admitted for the third time on Aug. 21st, 1886. From her leaving the hospital in March until the day of admission, there had been little or no blood in the urine. On that day hæmorrhage came on badly, and the patient therefore sought admission. She was extremely pallid and wasted. A mass could now be felt in front and to the left of the uterus.

On the 24th the bladder was opened as before, through the anterior vaginal wall. There were polypoid growths from the vesical wall, which were removed as far as possible; but there was also much thickening at the base of the bladder. The patient was given a dose of brandy before the administration of the anæsthetic, and another after the operation was finished. She did not seem greatly exhausted. She, however, gradually sank, and died about twenty-four hours afterwards.

The necropsy showed cancer of base of bladder; large multilocular cyst of right ovary, and small one of left ovary; secondary cancerous growths in liver and lungs; uterus healthy; kidneys healthy.

Remarks by Dr. HERMAN.—This case is thought worth publishing as an instance of a rare form of disease—primary cancer of the female bladder. Cancer of the bladder arising by extension of cancer beginning elsewhere is common. According to statistics collected by Féré,[1] the most usual place for primary cancer of the bladder is the base, and next most frequent the posterior wall. In this case the growth began in the base, and when this had been removed fresh growth took place from the posterior wall. As in most cases of the kind, hæmaturia was the most prominent symptom, and the anæmia produced by it the source of most distress and danger. The disease seems, from the history, to have commenced with cystitis: not a common mode of origin. According to Féré, it is rare for generalisation to take place, the local accidents usually causing death, and the average duration of the disease is from eighteen months to two years. Judged by this standard, this case was one exceptionally protracted in its course, and one in which treatment was unusually successful. That the growth, which began in the base of the bladder, was completely removed is evidenced by the fact that at the second operation the growth causing hæmorrhage was from the posterior wall, and not at the place from which a growth had been removed at the first operation. Each operation was temporarily successful in relieving the patient, by stopping hæmorrhage, and they prolonged her life sufficiently for generalisation to take place. The ovarian tumour was not removed, because when the patient was admitted it was thought better to postpone operation for it (as it was not causing distress) until the patient's general condition was better. As time went on it was found by frequent measurement that the tumour was not increasing, and the patient's condition never became what would be desired for a subject of abdominal section. The case illustrates the best method of dealing with intra-vesical disease in the female. It has been often advised and practised to deal with disease of the kind by dilating the urethra, and reaching the interior of the bladder through this canal. This method is far inferior to that of cutting into the bladder through the vagina. It gives less easy access to the disease, and brings with it danger of permanent loss of control over the bladder. If the bladder be cut into from the vagina in the middle line, no important structure can be wounded, the inside of the bladder can be easily reached, and anything required done. The wound made by an incision is easily closed by sutures, in this respect differing from the vesico-vaginal fistulæ which sometimes follow labour, and are due to loss of substance from sloughing. But where there is cystitis it is beneficial to leave the wound open, so that urine and any débris may escape through it. This conduces to the comfort of the patient and the restoration of the bladder to a healthy condition, and the wound will often heal without sutures. Except for diagnostic purposes, for which it is not necessary to dilate further than required to admit the finger, incision of the bladder from the vagina should always be preferred to dilatation of the urethra.

CHESTER GENERAL INFIRMARY.

LARGE STRANGULATED UMBILICAL HERNIA; OPERATION DEATH; NECROPSY.

(Under the care of Mr. TAYLOR.)

THE notes of the case are by Mr. Alfred Mann, visiting surgeon.

George M——, aged fifty-three, was admitted at 4 A.M. on Sept. 15th last, suffering from a very large umbilical hernia, which had been showing signs of strangulation some four or five hours before admission. The patient was too ill to give a very full account of his previous history, but it appears that he had suffered from a large umbilical hernia for sixteen years, and had never experienced any symptoms of strangulation before, although never wearing any kind of truss or support. He had been a butler in a gentleman's family for some time, but for the last year or two had had no settled occupation.

When admitted the patient was not vomiting, but had been doing so an hour or two previously. He had considerable pain in the tumour, especially when pressure was made at the margins. The tumour itself was very tense and nodulated, giving the idea of adhesions existing between the contents and coverings of the hernia. It measured 39 inches round its base and 18 inches across at its broadest part. Previous to admission the patient had had five-sixths of a grain of morphia injected hypodermically. The symptoms were not very acute on admission, and under the influence of morphia the pain became much less. At 9.30 A.M. he was seen by Mr. Taylor. He had then just vomited some greenish-looking fluid with a foul smell, but not stercoraceous; the pain also had become greater, and the tumour more tense. By 11 A.M. stercoraceous vomiting had occurred. A consultation was held at 12.30, and herniotomy decided on.

At 3.15 P.M. the patient was put under chloroform, and, with careful antiseptic precautions, Mr. Taylor made an incision about six inches long over the tumour a little to the right of the middle line. The coverings of the hernia were separately slit up on a director, and the sac opened. This was immediately followed by a protrusion of a portion of its contents. A small opening was unintentionally made in the intestine, which caused the ejection of a large quantity of dark, foul-smelling fluid. The neck of the sac was found, and notched downwards with a hernia knife. No attempt was made to return the intestines into the abdominal cavity, but great difficulty was experienced in returning them into the sac. It was only by squeezing out the fluid contents through the opening that had been made in the gut that this could be effected. The intestine having been returned, the sides of the intestinal opening were stitched to the abdominal parietes so as to form an artificial anus, and the wound closed with strong wire sutures. Hypodermic injections of morphia were given after the operation, but the patient soon had a return of the stercoraceous vomiting, and died at 11 P.M. The temperature was subnormal after the operation up to the time of death, which took place rather suddenly.

At the post-mortem examination held on the following day, all the intestine contained in the hernial sac was found to be very much inflamed, and numerous adhesions existed between the contents and the sac. A white line on the intestine showing where the constriction had taken place was found at a distance of three feet from the stomach. The sac itself contained all the ileum, cæcum, and ascending and transverse colon. All this mass of bowel had become bent over the narrow opening into the sac. No fæcal fluid had escaped into the abdomen or into the sac.

DUNDEE ROYAL INFIRMARY.

SUPPURATIVE GASTRITIS; DEATH; NECROPSY.

(Under the care of Dr. MACLEOD.)

WE are indebted to Dr. Wilson, house-surgeon, for the notes of the case.

C. S——, labourer, aged sixty-three, was admitted in the afternoon of Nov. 16th, 1887, suffering from a supposed first attack of acute rheumatism, brought on by cold. His previous health was good, but he was addicted to the free use of stimulants. About a fortnight before admission he had a rigor, followed by pains all over his body, and pyrexia; the joints of the arms and legs were subsequently affected.

The patient on admission was well nourished; arteries atheromatous. He was suffering from pains in the joints of the arms and legs, increased by movement, but not attended by swelling or redness. Apex beat of heart in fourth interspace, in nipple line; dulness normal. Heart sounds at apex: first sound slightly muffled, also at the base. Percussion clear all over the lungs. Pulse 92, soft; temperature 102·4°. Appetite fair. Tongue dry, and covered with a white fur. Bowels regular. Ordered five grains of iodide of potassium and fifteen grains each of bicarbonate of potash and salicylate of soda every hour for four hours in water.

Nov. 17th.—Morning temperature 98·8°. Urine: sp. gr. 1020, acid, and high coloured; moderate albumen. Dr. Macleod saw the patient for the first time about 11 A.M. He was perspiring freely, with an anxious expression of countenance. Heart sounds natural. Complained of pain in the joints of the arms and legs; no swelling or redness. His mind was confused, and he was labouring under a busy delirium, closely resembling delirium tremens; this was attributed to the salicylate, which was discontinued. Evening temperature 99·2°. Patient noisy and semi-delirious, calling out and trying to get out of bed; all the pains gone. At night the patient began to get very violent, shouting and moving himself about, with delusions and other symptoms of delirium tremens. Forty grains of bromide of potassium were ordered to be taken at once, followed by twenty grains every two hours.—8.45 P.M.: Still as excited as he was at 5.30. Ordered a quarter of a grain of morphia hypodermically.—10.30 P.M.: Noisy and delirious; getting out of bed. Tied in bed, and a third of a grain of morphia given. Went off to sleep in about half an hour, and continued quiet during the night.

18th.—At 2 A.M. the patient was breathing naturally as if in a sound sleep. About 7 A.M. the nurse noticed that his breathing was noisy and stertorous, with rattle in the throat. On examination, pupils were found contracted; no response to stimulation either of the eye or skin. Pulse 132; respiration 28; temperature 104·2°. Rigidity of limbs on right side; left arm and leg flaccid. His head was ordered to be raised and an ice-cap applied.—8.30 A.M.: Temperature 106·2°; pulse 144; respiration 36. Condition much the same. Breathing stertorous. Pupils contracted and fixed. About fifteen ounces of blood removed from arm by venesection. Died at 10.15 A.M.

Necropsy, by Dr. Stalker, pathologist.—Nothing abnormal found in brain. Recent lymphy effusion between arachnoid and pia mater. Heart normal in size; one pericardial adhesion. Narrow liver. A string an inch long from the parietal and visceral layer on left ventricle, also recent vegetations on aortic cusps. Kidneys and spleen normal. Stomach greatly thickened all over greater curvation and round pylorus, where the wall was about an inch thick. On section the stomach wall was found to be divided up into spaces full of yellow pus, between the muscular layer and submucous membrane. Mucous membrane apparently healthy.

Remarks by Dr. MACLEOD.—Gastritis phlegmonosa, or diffuse suppurative gastritis, is a very rare affection almost impossible to diagnose, and very few text-books contain any reference to the disease. Ziemssen, in his "Practice of Medicine," relates one case, the symptoms being pain in the stomach, gradually increasing, vomiting, diarrhœa, general prostration, delirium, ending in coma. In the present case all these symptoms were absent, with the exception of [illegible] ended in coma, and closely resembled [illegible]. The symptoms resembled an attack of [illegible] and the busy delirium I found the patient [illegible] the only time I had an opportunity of [illegible] attributed to the action of the salicylate [illegible] another case of rheumatism. Post-mortem examination, however, disclosed the true state of matters, and the symptoms considered to be rheumatic were doubtless due to pyæmia. The patient was intemperate in his habits. In the absence of post-mortem examination, the case would have been described as one of acute rheumatism, ulcerative endocarditis, and hyperpyrexia.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Fatty Degeneration of Heart from Intra-abdominal Pressure.—Arsenic Cancer.—Stricture of Intestine following Tubercular Ulceration.—Avian Tuberculosis.—Syringomyelia.—Ulcerative Colitis.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., President, in the chair.

Dr. BEDFORD FENWICK read a paper on Cardiac Degeneration due to Abdominal Disease. He related the case of a woman aged forty-five, who had been married twenty-two years. She presented a uniformly distended abdomen; the cardiac sounds were dull. The ovarian tumour was of great size and solidity, and weighed twenty-two pounds after all fluid had been discharged. The operation wound healed by first intention, but on the eleventh day the patient became very ill and peritonitis set in, followed by death on the twelfth day. The heart muscle was pale, yellow, soft, and friable; the wall of the right ventricle was very thin, but the wall of the left ventricle was of natural thickness. The microscopic sections were made by Dr. Norman Dalton, and showed fatty infiltration and degeneration of the heart muscle. He believed that such a condition could cause rapid death and collapse, and, in fact, was the pathology of twenty-two fatal cases in which the general condition was well marked. He suggested that the effects of direct pressure were the probable causes of the degenerative change, which was proportional to the duration and size of the abdominal mass; such a physical explanation being obvious, there was no need to invoke more obscure agencies. The majority of cases occurred under the age of fifty, and yet fatty degeneration of the ordinary kind was most frequent in males above that age.

Mr. JONATHAN HUTCHINSON made a communication on Arsenic Cancer. The suggestion was made that the administration of arsenic for many years in full doses, as given in cases of psoriasis, could lead to the development of epithelial cancer, having some peculiarities. He showed a drawing of a foot which at first sight might have been thought to be a perforating ulcer, but there was no sinus and no other evidence of its being of this kind. Excision was practised, and the tissues treated with chloride of zinc. It was proved by microscopic examination that the disease had many of the characters of epithelial cancer. There were numerous little corns on the sole of the foot and in the palms of the hand, and undoubtedly due to the use of the arsenic. Microscopically, there was nothing definite as to its being an epithelial cancer. A case was mentioned which occurred in a member of the medical profession; the rough condition of the palms and soles, with the association of soft corns, was well marked. This condition did not develop as a papillary form. After suffering for some years from this condition of the palms and soles, there appeared on the front of the wrist of one hand an ulcer having some of the aspects of a syphilitic sore, but this was negatived on good evidence. The tumour was removed, but it grew afresh on each separate occasion. A course of anti-syphilitic treatment did no good. Amputation of both hands was performed. The patient lived for eighteen months, and died with epithelial cancer in the lungs, supra-clavicles, kidneys, and a rib; these had the characteristic epithelial structure. Such a case tended to prove that arsenic could produce the palmar condition, and perhaps also the cancer. Another case had no skin disease whatever until he took arsenic for a cancerous growth in the neck; arsenic was taken in doses of twelve minims, three or four times a day; a muddy and thick condition of the skin appeared. In another instance, in a female child with pemphigus, where arsenic was prescribed in large doses, a cancer developed on the skin over the crest of the ilium and under the skin of the thigh; it ulcerated, and the patient died at the age of

Digitized by Google

twenty-five. Another instance was noted by Mr. Waren Tay, in a clerk aged thirty-four, who had psoriasis and developed a cancerous mass on the scrotum of epithelial sort after taking large doses of arsenic. Altogether, the cases, he thought, went to show that arsenic might and could be a powerful factor in the development of cancer in certain cases.—Dr. EDMUNDS said that in the fens of Cambridge arsenic was taken in large doses for ague, and yet cancer was rare. There was no ague, but cancer was prevalent in Norfolk, where arsenic was presumably not used. He thought that coincidence would explain Mr. Hutchinson's cases.—In reply to a question, Mr. HUTCHINSON said that the arsenic was stopped in the case of the medical man as soon as it was suggested as the cause of the cancer.—Dr. HADDEN said that skin eruptions produced by arsenic were not mentioned in text-books.—Mr. HARRISON CRIPPS said that further evidence was wanted. In the first case, resembling perforating ulcer, the microscope showed that the disease was not epithelial cancer. The psoriasis in the medical man might be regarded as the cause of the cancer from chronic irritation.—Mr. MAKINS suggested that information from Styria would be of value.—Mr. F. S. EVE said that epithelial cancer took on a peculiar form in the palms and soles. In workers in cobalt mines lympho-sarcoma of the lungs and submucous tissue developed. He could perceive no reason why arsenic should not in a similar way set up carcinomatous disease.—Sir JAMES PAGET considered that arsenic might have some influence in accelerating or producing cancer. The whole characteristics of the disease should be taken into consideration in determining its nature; the microscope could not always be trusted in diagnosis. The evidence went to show that arsenic had a very definite influence in the causation of the cancer.—Mr. JONATHAN HUTCHINSON, in reply, said that Dr. White of Harvard University believed that the case was one of psoriasis-cancer. It was exceptional for psoriasis to affect the palms of the hand, and yet arsenic produced the rough and horny condition of this region. In the diagnosis of cancer he would not trust to microscopical evidence. In the case of the medical man continental authorities said the disease was syphilis, so that the absence of microscopic evidence was not conclusive, because in this case at least cancer was certainly present. Arsenic could certainly cause herpes zoster and arsenical eczema; it did not produce symmetrical eruptions.

Mr. FRED. TREVES showed a specimen of Tubercular Stricture of the Colon, removed from the body of a boy aged fifteen years, who was admitted into the London Hospital with the symptoms of chronic intestinal obstruction of six months duration; diarrhœa, colic, and gradually increasing constipation were the chief symptoms. The patient became worse and developed peritonitis, which was treated as a last resource by enterotomy and the formation of an artificial anus in the middle line. At the necropsy the left lung showed caseous deposits at the apex. The stricture existed at the end of the ascending colon, and was of a dense circular fibrous character. Certain characteristics were sufficient to diagnose it as a tubercular ulcer: it was entirely circular, and in vertical direction measured 1½ in.; the contracting medium was the mucous membrane, and this membrane was dissected from the submucous tissue, with a formation of cloacæ, and fenestræ, and tags, fifty in number, some flattened and sessile, others branched somewhat similar to those resulting from undermining tubercular ulcers of the skin of the neck. The submucous tissues appeared to be the chief seat of the disease. The disposition to the formation of stricture was absent if the whole of the mucous membrane were destroyed. Tuberculous disease of this sort usually had very little disposition to form a scar.

Mr. W. SIBLEY read a paper on an Epizootic of Avian Tuberculosis in a farm in Surrey, and showed specimens of the various organs diseased. Much caseating matter was expelled from the bowel, after having been discharged into its lumen from the diseased walls of the intestine, and thus left behind large pouches. The lesions presented the typical forms of bacilli. The disease generally appeared when the birds were about two years old. The whole of the abdominal organs were effected. Mention was made of one such pouch connected with the crop which attained the size of a pigeon's egg. Subpleural nodules were also present, and the larynx and trachea were diseased. Vertebral caries and caseating cervical glands were occasionally observed. Bacilli, apparently identical with those found in human tuberculosis, were present in most of the affected organs. The nodules appeared to have little tendency to break down, but the growths tended to spread and to caseate, forming relatively large tumours. The disease was apparently an example of hereditary transmission.

Dr. CHARLEWOOD TURNER exhibited a specimen of Syringomyelia in the spinal cord of a female, aged twenty-three, who died in the London Hospital from a severe burn caused by falling into the fire during a fit. She had atrophy of the upper limbs, which had been developing for twelve months. There was a large central cavity extending from the medulla oblongata to the upper end of the lumbar enlargement, and a smaller cavity in the right posterior cornu in the lower part of the lumbar region and conus. The cervical enlargement was expanded by a large central cavity with processes along the posterior nerve roots to the surface of the cord. In the dorsal region the cavity was chiefly on the right side of the cord and was smaller. In the mid-dorsal region it was divided into two separate channels in the posterior grey matter of each side. Below, it became again a single channel, in part symmetrical, in part on the right side. When the cavity was central it was divided by an antero-posterior median septum of membrane. The lateral ventricles of the brain were dilated, the left anterior and posterior cornua more so, in correspondence with the predominance of the spinal lesion on the right side, emphasising the observed association of syringomyelus with hydrocephalus. Referring to Leyden's suggestion that hydromyelus arises from unobliterated portions of the posterior limb of the embryonic central canal, Dr. Turner expressed the opinion that the spinal cavity in such cases originated in dilatation of perivascular spaces in the neuroglia—(1) because of the limitation of the lesion, in part or wholly, to the cornua. The division of the channel into two lateral portions, and the presence of a median membranous septum dividing the channel where centrally situated, were indications of the origin of the cavity in the posterior grey cornua in the central extension rather than the contrary course; (2) because the ventricles of the brain, as in a sense perivascular cavities, are, physiologically and functionally, in correspondence with the perivascular spaces in the cord, and become distended in hydrocephalus through serous exudation from the vessel in excess of the outlet of escape; and the watery character of the fluid in syringomyelus shows that this is similarly due to exudation, whereas distension of a closed epithelial tubule in the connective tissue of the cords, though intelligible as a result of the formation of some mucous or colloid substance from the epithelial surfaces, is not intelligible as a result of exudation from the vessel.

Dr. HALE WHITE showed a specimen of Ulcerative Colitis from a man who died with a history of diarrhœa, melæna, vomiting, abdominal pain, and wasting, of a few months' standing. No cause could be found. At the necropsy it was discovered that there was ulceration of the whole of the large intestine, beginning at the cæcum and extending to within four inches of the rectum. The ulceration was universal, leaving, however, irregularly shaped islets of swollen congested mucous membrane. The edges of the ulcer were sharply defined; the floor consisted of exposed transverse muscular fibres. There was no attempt at repair or perforation, no peritonitis or tubercle. The ulceration was least marked in the cæcum and rectum. Dr. Hale White pointed out that, although this condition was occasionally met with, nothing was known as to its origin beyond the vague speculation that it arose in either a follicular or catarrhal ulcer; nor was anything known as to its cause, for it was certainly distinct from dysentery. It appeared to be invariably fatal, and its presence could not be detected during life with any certainty.

The following card specimens were exhibited:—

Mr. MAKINS: Primary Cancer of Bladder.

Mr. BULL: Bladder from case of Prostatectomy and Suprapubic Lithotomy.

Dr. HEBB: (1) Tricuspid Disease—five specimens; (2) Fowl Tuberculosis; (3) Bacilli in Diphtheria.

Mr. F. S. EVE: Ranula illustrating origin from Nuhn's Gland.

MEDICAL SOCIETY OF LONDON.

Cardiac Failure in Pulmonary Obstruction.—Chyluria.

AN ordinary meeting of this Society was held on Dec. 5th, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Dr. THOROWGOOD, in order to keep his paper on Cardiac Failure in Pulmonary Obstruction within due limits, confined his observations to the best methods of assisting a weak and

Digitized by Google

failing heart under the difficulty of pulmonary congestion and obstruction. It was quite true, as said by many authorities, that cardiac failure was the great cause of death in pneumonia and many other respiratory diseases. Dr. Thorowgood did not agree with Felix Niemeyer that stimulation of the heart must increase the amount of œdema already existing on the alveoli of the lungs in pneumonia; but he did think, from what he had observed, that stimulants were often given too freely and too early in the course of the disease, to the neglect of other remedies. This fact was brought out most in cases of bronchial or catarrhal pneumonia, a disease in which respiratory insufficiency is the principal cause of death. Too much stimulant tended to gorge the right heart with blood, and so did but increase the respiratory distress. In a case narrated, a child aged seven years had a severe attack of catarrhal pneumonia supervening on whooping-cough. When seen she was livid in the face, hardly conscious, and the lungs were full of coarse râles. Champagne and brandy had been freely given, with no benefit. All stimulants were withdrawn, and under the influence of small doses of tartarated antimony in conjunction with sulphate of magnesium, the child made a good recovery. Dr. Thorowgood fully admitted the value of alcohol as a cardiac stimulant, but in cases of bronchitis and pneumonia he considered it important to begin with such a medicine as tartarated antimony with a saline, the intention of this plan being to relax the capillaries, promote secretion, and so lessen the labour entailed upon the heart, the principle being much the same as when we sought to aid a heart failing in an attack of angina by dilating the capillaries with nitrate of amyl. No remedy would equal the tartarated antimony in repeated small doses. The earlier it was given the better; but even in advanced cases it might often be employed with striking effect. It seemed to have, as Stokes of Dublin once said, a specific action over the capillaries of the lung. In small doses it might be stimulant, while in excessive doses it might paralyse, and so cause that congestion of the lungs which Majendie had observed in animals poisoned by the drug. As direct respiratory stimulants, belladonna, nux vomica, and carbonate of ammonium were remedies of proved and undoubted value.—Dr. ROGERS had seen benefit follow the administration of small doses of tartar emetic combined with iodide of potassium.—Dr. ROUTH spoke of the value of nitro-glycerine given with carbonate of ammonia as a cardiac stimulant. He referred to Claude Bernard's treatment with intra-tracheal injections, which went to show the marked absorbent power of the pulmonary mucous surface.—Dr. S. H. HABERSHON said that the rapid effect of strychnia as a motor stimulant was brought out by hypodermic injection, and he alluded to a case of double pneumonia which was greatly benefited by the subcutaneous administration of 1-60th of a grain of the acid sulphate.—Dr. THOROWGOOD, in reply, objected to venesection on the ground that its effect was only temporary. He had found that strychnia prevented pulmonary œdema.

Dr. STEPHEN MACKENZIE read a paper on Chyluria, with remarks on the *rôle* of the Mosquito, and a description of a Nematode Worm in the Urine, mistaken for the Filaria Sanguinis Hominis. The author began by describing a case—that of a gentleman from the West Indies, who had suffered from chyluria since 1876 on and off, and possibly his disease dated much further back, to the age of nine or ten. His urine when first passed was of a rich chocolate colour, but when the blood corpuscles subsided it was left of a rich creamy-milk appearance. It was acid, sp. gr. 1025, contained 0·6 to 0·7 per cent. of albumen, and was free from sugar. It contained no casts. When shaken with ether the suspended fatty matter was removed. After taking benzoate of soda in 80-grain and later in 45-grain doses, it quickly became quite clear. When his blood was examined by day no filariæ were found, but when examined at night living embryo filaria sanguinis hominis were always present. The filariæ were not deceived by a London fog into entering the general circulation in the day-time. He had suffered from what he called "intermittent fever," which Dr. Mackenzie pointed out was probably filarial and not malarial. He also had some enlarged vessels in the groin, which, it was conjectured, were dilated lymphatics—"nævus lymphaticus"—and were probably due to a parasitic habitation in this region. The leaking of the lacteals into the urinary tract probably took place in the kidney in this case. Passing on to the consideration of the *rôle* of the mosquito, the author pointed out how this insect fulfilled the necessary requirements of an inter[me]diary host, by its geographical range, and by its habit of [fee]ding at night when the filariæ were in the blood. It [was], he said, been clearly demonstrated that only a certain [spe]cies of mosquito was capable of nurturing the filaria. [It] had been urged that there was no necessity for a suctorial [in]sect, as the embryos could escape with the urine. It was [sho]wn, however, by the author that the urine was an unfa[vou]rable medium for the embryos, and therefore an unlikely channel for their distribution. He next briefly described the changes taking place during the stay of the [fila]ria in the mosquito, and demonstrated most of these [stag]es from preparations sent by Dr. Manson. Lastly, he described a nematode worm that had been found in the urine in two cases, and mistaken for the filaria sanguinis hominis. He pointed out that it was a bisexual mature worm about 1-30th of an inch long by 1-500th of an inch broad. It was probably a variety of Dujardin's species, Rhabdonema, but how it got into the urine he had no explanation to offer. In conclusion, he pointed out how practically important it was for cases of chyluria occurring in this country to be due to filaria sanguinis hominis, or for the latter to, in any circumstances, get into the urine or blood of persons who had never left this country.—Dr. THEODORE ACLAND said that when in Egypt he met with a case of hæmaturia caused by a nematode worm, which he was unable to identify.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A MEETING of the above Society was held on Friday, Nov. 18th, Dr. ALFRED HILL, President, in the chair.

Dr. W. N. THURSFIELD read a paper entitled, "Pasteur's System of Preventive Treatment of Hydrophobia," of which the following is an abstract:—A medical officer of health was liable, if not *ex-officio*, at least by custom, to be called upon at any moment to give responsible advice on the important question, "Should an individual bitten by an animal presumably rabid, undergo the Pasteur system of preventive inoculation?" and his object in the following communication was to endeavour to contribute some evidence towards arriving at a sound conclusion on this question. He endeavouring to show how far statistical evidence of results justify confidence in the Pasteur system of treatment, he thought it would be well to remove certain false impressions and misrepresentations which are constantly repeated with reference to the work at the Pasteur Institute, and he regretted with regret that in the recent report of the evidence before the Select Committee on Rabies of the House of Lords, several of these misstatements reappear. To the statement frequently made, that any person offering himself for inoculation at the Pasteur Institute was received and treated without any proof whatever that the dog was rabid, he could give a most emphatic denial. In every case satisfactory evidence that the dog was rabid is required, and when practicable patients were requested to bring or forward the head of the dog. He had himself seen a patient bitten by a dog-bite, but there being no evidence that the dog was rabid, he was refused inoculation, and treated as for an ordinary bite with local applications. In the case of each patient, before commencing the inoculations, full particulars were taken, and a consultation then held by the staff of the Institute as to a line of treatment, which was separately prescribed for each patient on his allotted page in the case-book. In arriving at the prescription, the age and diathesis of the patients, the extent, and nature of the bite, and other matters were considered, and the number, date, and strength of the inoculations were then prescribed, subject to variation or extension if circumstances should make it desirable during the course of treatment. The utmost care and most scrupulous precautions were taken to preserve an aseptic condition, both of the inoculating fluids and of the instruments employed. The syringes were of glass, silver-mounted and with needles of steel, and new syringes were used for each series of inoculations. After each separate inoculation the needle of the syringe was plunged into oil heated to a temperature above that of water, by means of a chloride of calcium bath, and the needle being again plunged into the inoculating fluid the piston of the syringe was passed through sterilised filter paper. And after each series of inoculation the syringe was at once sent back to the maker. These precautions were taken in order to have all its absorbent portions removed and thoroughly cleansed and refitted. Dr. Thursfield then came to the

Digitized by Google

a most important point, and one which, and not the real merits of the case, was at the bottom of the most active opposition to the Pasteur system of treatment and of the abuse showered on those who ventured to countenance the system. He alluded to the question of cruelty, and he would endeavour, from his own experience, to show on what a baseless foundation this idea of cruelty, at the Pasteur Institute rests. The practical work of the Pasteur Institute consisted: 1. Of inoculations of rabbits with rabid matter for the preparation of inoculating fluids for treating human beings bitten by rabid animals. Three rabbits were daily so treated. 2. Test inoculations, chiefly performed on guinea-pigs, with a view to test whether animals which had been killed as presumably rabid were really so. 3. Collateral test investigations as to the power of inoculating fluids to prevent the development of rabies &c. The first two proceedings were the only ones absolutely essential to the practical working of the Pasteur system as at present developed, but it was to the third that was due the foundation of the whole system. The inoculations were either intra-cranial or sub-cutaneous. The intra-cranial inoculations were invariably carried out under complete anæsthesia, and with precise antiseptic precautions. As much care was in every case taken, both as regards anæsthesia and antisepsis, in the case of the animals experimented on, as was done in the case of a human being in the best-ordered London hospital. In every case that he saw, the wound healed by first intention, and as soon as the animal had recovered from the effects of the chloroform, in a quarter of an hour or so it would generally eat. As regards the time occupied by the whole proceedings involved in the operation of intra-cranial inoculation, he timed a number of operations, and found that the average time from the moment the animal was placed under restraint until it had recovered from the anæsthesia and was released was as nearly as possible five minutes, of which between ninety and one hundred seconds were taken to produce complete anæsthesia, and the time occupied by the operation itself from the first incision till the wound was sewn up averaged two minutes and ten seconds. As regards the operation of subcutaneous inoculation, although technically vivisections, little pain was involved. This was evident from the fact that the only restraint necessary in dogs was for an attendant to hold the animal between his knees, merely restraining its fore-paws with his hand with occasionally the finger and thumb of one hand placed round the mouth. The demeanour of the dogs generally seemed to indicate quite as much pleasurable anticipation of the lump of sugar which always followed the operation as impatience of the restraint, and he could state most positively that he had seen a dog wag its tail during the whole proceeding. As to the after-results of the inoculations, it was certainly painful to see an animal suffering from purposely induced disease. To take the extreme case of the rabbits, where fatal rabies is the invariable result of the operation, and three of which were inoculated daily, they commenced to sicken on the sixth day after the operation, and died on the ninth. As a matter of fact, they did not seem to suffer much pain. The first symptom is apparent dulling of the mental faculties accompanied by paralysis of the extensor muscles of the hind legs. The paralysis and the dulling of the mental faculties proceeded side by side, and the rabbit died comatose and with general paralysis. He had so far endeavoured to show that as regards careful and conscientious work, carried out on a thoroughly scientific basis, the Pasteur Institute was in every way worthy of confidence. For evidence as to the success obtained they must go to statistics. Statistics there were in abundance, not only from the Pasteur Institute in Paris, but from the Anti-rabic Institutions in Russia, several of which had now been some time in full work; but to properly consider these statistics would necessitate the critical examination of so many points and so many distinct cases that a much larger time than that at present at his disposal would be insufficient. He should therefore confine himself to the statistics of the present year, and chiefly to those of the first six months of the year—that is, up to the end of June; this would ensure that a minimum period of four months would have elapsed since the bite in each case, and in the large majority of the cases a period of over six months. This would cover the ordinary period of incubation, but not the exceptional, though by no means rare, cases in which the incubation was prolonged. From Jan. 1st to Sept. 30th, 1887, 1392 persons had been inoculated at the Pasteur Institute. These 1392 persons had been bitten by the following agents: Dogs, 1294; cats, 74; wolves, 11; pig, 1; donkeys, 4; cows, 3; calves, 2; horses, 2; ox, 1; tame fox, 1; jackal, 1; mule, 1; human being, 1. In 1182 of the persons treated the rabid condition of the animal causing the bite had been shown, either by experimental inoculation, by the fact of some animal or person bitten at the same time developing rabies, or by the certificate of competent veterinary authorities. In the case of the remaining 210, the animals had been suspected of being rabid from symptoms exhibited during life. From January 1st to June 30th of the present year 954 cases were inoculated, and in the case of 805 of these the rabid condition of the animals causing the bite had either been proved beyond question, or certified by qualified veterinarians. Of the above 805 bites, 581 were inflicted direct and without the intervention of clothing, and 69 were on the head or face. A large proportion of the fatal cases were bitten on the face. Up to Oct. 15th, 1887 (after which he had no information), so far as is known, 15 of the above cases had developed hydrophobia, and, taking the percentage on the 805 persons only, this gave a result of less than 2 per cent.; but some of the cases should not fairly be included, having commenced treatment too late. Of the above 15 cases, 3 were British subjects, who had commenced the treatment on the twelfth, eleventh, and sixth day after the bite respectively, and 4 were Spanish subjects, who had commenced the treatment on the thirteenth, thirteenth, eleventh, and twenty-eighth day after the bite respectively. The remaining 8 cases were French subjects, who as a rule commenced their treatment in good time. Now, he was by no means prepared to say that the treatment was inoperative unless commenced before ten days had elapsed, but he attached much value to Mr. Horsley's opinion, that if the inoculations were commenced after the tenth day they were probably too late, and it was certainly not an unfair use of statistics to exclude all such cases. This would bring the mortality down to 10 in 805 cases selected as bitten by animals declared to be rabid on the best authority, or just 1·2 per cent.—In the discussion which ensued, the President, Drs. Drysdale, Saunders, and Renner, Mr. Wynter Blyth, and Mr. Shirley Murphy took part, and Dr. Thursfield replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Hour-glass Contraction of the Stomach.—Phlegmasia Alba Dolens.

THE opening meeting of the Pathological Section of the Academy was held on November 4th, when the President delivered an address on Tetanus.

Dr. FINNY exhibited a specimen of Hour-glass Contraction of the Stomach, occurring in an organ which was the seat of several ulcers. The following were the clinical history and the morbid appearances. Mary M'G——, a domestic servant, aged twenty-nine, was admitted into Sir Patrick Dun's Hospital on May 13th, 1887, in a state of collapse and in great pain, which was referred to the lower part of the abdomen. After reaction had set in, under appropriate treatment, she vomited once, and the rejected matter consisted of tea and milk, but contained no blood. The urine was drawn off, and found to be free from albumen and indican. All her symptoms were those of acute peritonitis from perforation. Death ensued eight hours after admission. Her history was to the effect that she had enjoyed good health up to three weeks previously; but, beyond some slight dyspepsia, she was able to continue her duties as a domestic servant up to the day before admission. The post-mortem examination, made thirty-six hours after death, displayed acute general peritonitis, with flaky lymph and seropurulent fluid, while the stomach was found to be the seat of recent inflammation, as well as of old and firm adhesions to the liver, spleen, pancreas, and diaphragm. At first sight there seemed to be two stomachs, or one with a very dilated duodenum; and this appearance was due to a transverse constriction of the stomach, nearer one-third to the pylorus than to the cardia. On the anterior surface of the cardiac half of the organ, not far from the greater curvature, the origin of the general peritonitis was seen in the existence of a circular, sharply defined, perforating ulcer, the size of a threepenny-piece. On laying open the stomach it was found to have been the seat of several ulcers—(1) that referred to on the anterior wall, which on the mucous aspect measured a sixpence, and had the punched-out characteristic appear-

Digitized by Google

ance; (2) a firmly cicatrised, circular ulcer on the posterior wall, near the lesser curvature—which was not in a state of activity—whose floor consisted of the pancreas, to which it was adherent; (3) a small ulcer in a stage of activity lower down in the posterior wall; and (4) an oval ulcer extending three-quarters of an inch from the lesser curvature, transversely to the long axis of the stomach, and in an active stage of destruction of the mucous and part of the muscular coat. This ulcer ran into the circular constriction, which divided the stomach into two unequal bags. The constriction, which was half an inch wide, narrowed the organ so as to admit but three fingers, and had all the appearance, from external examination, of the pylorus. The lesser curvature was not dimpled or much marked, but towards it the greater curvature was drawn at this spot, so as to make two bags of the stomach. Its outside was thickened by old lymph, while on the inside the rugæ of the stomach seemed to run into it, and at its cardiac side was the ulcer referred to as No. 4. Dr. Finny discussed the pathological origin of the constriction, and remarked on its want of agreement with the features depended upon by Dr. W. R. Williams as distinctive of congenital hour-glass contraction. He alluded to the rarity of cases of this deformity of the stomach, the greater number having been discovered in the dissecting-rooms. He also laid stress upon the following, as exemplified by his specimen—(1) the comparative greater danger of an ulcer situated with anterior wall; (2) the coexistence of three ulcers in a state of activity; (3) the possibility of relapse; (4) the encouragement to treatment to be derived from the fact that so many ulcers—about half of those recorded—have been discovered in a state of cicatrisation. There was no history of food having been taken immediately before the occurrence of the great pain. The woman had never complained of any pain in the stomach, or other marked gastric symptom, until three weeks before her admission. She was doing her work as a servant when the sudden occurrence of pain obliged her to seek relief. The case was an example of ulcers painlessly eating their way through the walls of the stomach, and ending in perforation at short notice. The woman had vomited before she came into the hospital, and in consequence of the small size of the opening caused by the fatal ulcer nothing was extruded through it.

Professor BENNETT submitted a specimen of Phlegmasia Alba Dolens. The patient, a girl of fifteen years, was admitted on Sept. 30th, 1886, into Sir Patrick Dun's Hospital, and remained there until June 27th, 1887, when she died. When admitted she had phlegmasia alba dolens in the whole of the left leg, which was distended with white œdema. She was extremely emaciated and anæmic, and her œdemic leg was in strong contrast with the rest of her body. There was great difficulty in assigning any cause for the ailment, pregnancy and parturition being entirely out of the question. She suffered from great gastro-intestinal irritation, which was complicated with vomiting and diarrhœa, accompanied with pain. Three weeks after her admission œdema of the right limb commenced, and the condition of the right leg soon became the same as that of the other. Diagnosis then became easy, it being apparent that there was obstruction of the femoral and iliac veins, and that it had extended up the involved vein on the right side. Clinically the case was an extremely easy one to read, and before the swelling of the right limb occurred it was prognosticated that it would occur. The femoral vein could be felt hard and distended on the left side, and when the œdema on the right side occurred the vein on the opposite side was as firm and hard under the finger as a cord. After this, without any material change in the general system, collateral circulation of the venous system of the abdomen began to establish itself, with a reversal of the blood currents, these being directed towards the thorax instead of the groin. There was then some slight clearing up of œdema, and just a prospect of recovery. Still the gastro-intestinal irritation remained. Then suddenly there came an accession of symptoms, indicating uræmic poisoning. Then there was rapidly developed extreme œdema of the whole body, which pitted rapidly; and finally, with uræmic phenomena, death took place. He would now show what they had guessed at as the cause of the disease, but could not distinguish with certainty. There were two great cylindrical patches, close to each other, in the lower portion of the small intestine, of tubercular ulceration of the intestine, with a great series of enlarged glands infiltrated with tubercular matter occupying the mesentery. There was no tuberculosis of the lung; but the gastro-intestinal phenomena appeared to be produced entirely by the condition of the small intestine. The femoral veins and tributaries were occluded. The vena cava inferior was a complete fibrous cord, shrunk and flattened out. When it was traced up between the kidneys there was found a large, firm thrombus, which had already undergone calcification. Then came the most interesting point in the case. On the surface of the calcified thrombus, and projecting up the occluded vein, with its base between the veins of the kidneys, was a fresh, newly formed thrombus superadded upon it. These thrombi had extended into the renal veins, which were completely occluded in their paths towards the kidneys; and the greater number of the small branches in the substance of the kidneys were also absolutely and entirely occluded. By the second deposit of coagulum on the basis of the old thrombus, and its recent extension into both the renal veins, the fatal issue was brought about, accompanied by the uræmic phenomena of suppression of the urinary secretion, and the rapid development of general anasarca, which was absent in the earlier stages of the case.—Professor PURSER said the chief point of interest appeared to be, what effect the thrombosis of the renal veins produced on the secretion of urine. The idea generally held was that the quantity of urine secreted depended on the pressure of the blood on the renal capillaries. It was not improbable that the diarrhœa was due to degeneration of the bloodvessels—amyloid degeneration; and, if so, the condition of the kidneys would not have been of such a kind as to make the change in the circulation of any value, one way or the other, as regarded the secretion of urine.

The Section then adjourned.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the general meeting held on Nov. 4th, Mr. Edward Atkinson, President, in the chair, the following papers were read.

Dr. MYRTLE related two cases illustrating the occasional great difficulty of Diagnosis in the Earlier Stages of Malignant Disease. Case 1: A gentleman aged fifty-four, first seen on Aug. 4th, complaining of a sharp pain at the anus. Examination revealed nothing except a hæmorrhoidal condition, not severe. On Sept. 3rd, he was again seen. Pain worse, associated with severe neuralgic pain in the penis, diarrhœa, and marked deterioration of the general health and appearance. At a consultation, nothing beyond a ballooning of the rectum and laxity of the mucous membrane could be detected by the most careful examination. On the 20th he was seen by a distinguished London surgeon, who diagnosed inflammation of the cellular tissue between the rectum and prostate, and gave a good prognosis. Two days later he was much worse, and another examination revealed a hard nodulated mass high up in the rectum. The patient died on the following day, seven weeks after he was first seen by Dr. Myrtle. Case 2: The patient twelve months ago complained of a peculiar sensation at the lower end of the sternum on swallowing, and of shooting pains about the anterior chest wall, having special difficulty with certain acid fluids. For a time relief was obtained by the administration of cocaine in one-eighth of a grain doses before meals, but soon the dysphagia came on again, grew steadily worse, and hæmorrhage supervened. He was subsequently at various times examined in consultation by physicians and surgeons, and a throat specialist of the highest eminence, whose diagnosis included spasm, neuralgia, a small patch of inflammation and aneurysm of the aorta; and it was not until quite late in the case that a growth occluding the œsophagus and a mass occupying the cardiac end of the stomach were demonstrated. At this time there was complete obstruction of the gullet, and the patient was kept alive for twenty-six days longer by rectal feeding.—Dr. CLIFFORD ALLBUTT referred to the case of a patient who had been in a railway accident, and who was sent for an opinion by the solicitors, who were preferring a claim for damages. The main symptoms since the accident were: steadily continuous emaciation, colicky pain in the hypogastrium, and irregularity of the bowels. There was found upon examination a nodulated mass of malignant disease high up in the rectum. But in these apparently latent cases [illegible] important

Digitized by Google

point is the cachexia and wasting, being inconspicuous or absent in cases of spasm, inflammation, or neurosis.—Dr. EDDISON said that in his experience the surgical treatment of malignant stricture of the œsophagus was eminently unsatisfactory, the mortality of gastrostomy being almost prohibitive.

Dr. SCOUGAL read the case of a woman who after a normal labour was seized on the ninth day with pain on the right side of the head and numbness in the first three fingers of the left hand. This was followed by incomplete paralysis of the left side, with transient dysphagia. She gradually became comatose, and the loss of power more marked. Post mortem, a clot was found in the middle cerebral vein; none in any of the arteries or sinuses.—Dr. BRAITHWAITE, who had seen the case, had been unable to arrive at a satisfactory diagnosis. He remarked on the great variation in symptoms in such cases, and referred to a case recorded by Dr. Fordyce Barker, where a clot in the middle cerebral artery had been followed by no symptoms.

Professor DE BURGH BIRCH read a paper on the Analysis of Fluid which was secreted by the Gall-bladder, which had been opened by cholecystotomy in two cases. The fluid was thin and watery, containing no bile elements, but with a faint diastatic power. The ferment could not be isolated, but seemed to be held in the mucin, and was destroyed by acetic acid. The cases had been under observation for many months, and the fluid on every occasion presented the same characters.

Dr. ALLAN showed a case of Leucoderma in which the patches were symmetrical.

Dr. BARRS exhibited a case of Multiple Neuritis. The patient was a young girl, in whom the condition was associated with enlargement of the spleen and marked anæmia.

Mr. WARD showed a case of Generalised Non-ulcerative Gummata of the Skin, of six years' duration.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Nov. 10th, Dr. de Bartolomé, President, in the chair.

Rupture of the Trachea, followed by general Emphysema and Asphyxia.—Mr. GARRARD related this case. A girl aged eight fell on a sharp-edged slate hanging round her neck, bruising the front of the neck. She began to swell at once with emphysema, and was brought to the Rotherham Hospital about an hour afterwards. The emphysema had by then extended to every part of the body, to the fingers, and toes. She died a few minutes after admission. No post-mortem could be obtained, but a distinct depression could be felt just below the cricoid cartilage. Mr. Garrard much regretted that so much delay occurred in bringing the child to the hospital, and thought that, had an early incision been made over the trachea to the injured part, life would have been saved.

Paralysis of Third Nerve after Puncture of Upper Eyelid.—Mr. GARRARD related the particulars also of this case, occurring in a boy aged seven. The patient was introduced. A stick had penetrated the upper eyelid. Recovery from all symptoms had occurred, except that optic nerve atrophy had resulted.—Mr. Snell, Mr. Pye Smith, and Mr. James made remarks.

Amputation at Wrist.—Dr. T. H. MORTON introduced a youth aged sixteen, whose fingers and hand had been caught between hot steel rollers, and were severely crushed and burnt. Amputation of hand was performed at wrist joint; the pisiform bone was removed, but the articular surfaces of the radius and ulnar were left intact. Cellulitis and abscess of the forearm delayed recovery, but the result was a well-cushioned, serviceable stump.

Certain Considerations on Typhoid Fever.—Mr. WEDDELL read a paper with this title. The facts related were observed in the Queensland Emigration Service, and particulars of thirteen voyages were given. The history of the earliest and many subsequent importations of this disease into the Australian Colonies was described from official sources. The conclusions were that, whilst it appears certain that with a large number of people taken from various localities, it is possible, in spite of all precautions, that the germs or contagion of any specific disease may be introduced, yet there is little danger from typhoid on a properly ventilated ship, efficient sanitary measures being observed. The early detection and treatment of tropical diarrhœa was advocated. Even when a distinct link of contagion could be traced, no outbreak of any importance took place unless the people were exposed to conditions which impoverished the blood and exhausted innervation. The accounts of ships quarantined for typhoid seem to show that the putrefaction of filth in a confined space has often been an important factor in the spread of the malady.

Reviews and Notices of Books.

Experimental Researches in Artificial Respiration in Still-born Children and Allied Subjects. By FRANCIS HENRY CHAMPNEYS, M.A., B.M. Oxon., F.R.C.P. London: H. K. Lewis.

THE work before us deals with investigations of the greatest importance, and Dr. Champneys deserves the thanks of the profession for having devoted so much time and labour to the subject, as well as for the extremely able manner in which he has prosecuted his research and marshalled his facts. Like so many byways of medicine and surgery, which are not scheduled by the examining boards or seized upon by the fitful fashion of the hour, the resuscitation of the still-born and of persons in whom respiration is at a standstill has received most inadequate treatment by experimentalists, lecturers, and authors. Dr. Champneys deals only with the matter as regards still-born children, but of necessity he trenches upon the wider ground of the relative merits of the various systems of producing ventilation of the lungs by artificial respiration both in the still-born and in those who have breathed. The first chapter, which with some of the other parts of the book will be remembered as having been contributed to the Royal Medical and Chirurgical Society, gives some highly important and interesting experiments designed to ascertain which method —and nine are investigated—of artificial respiration produces in the still-born the fullest ventilation. Of these nine methods, it is not too much to say that four only are at all well known in this country—Marshall Hall's, Howard's, Silvester's, and Schultze's; of these, the methods of the two first-mentioned authorities are valueless for the resuscitation of the still-born. The actual appea to an experimental test of the remaining methods as far as the still-born are concerned showed that all methods dependent upon the elastic recoil of the chest walls are useless; while Silvester's method, and its modifications by Pacini and Bain, give the greatest ventilation. Schücking's plan Dr. Champneys found no improvement on Silvester; Schüller's and Schroeder's, he believes, are actually prejudicial, and Schultze's, although possessing considerable expiratory vigour, is not to be commended, since the force used in its employment is undesirable in dealing with infants. The question, "What portions of the lungs become expanded under artificial respiration?" was also experimentally tested, and conclusions interesting and important to clinical observers obtained. Chapters 3 and 4 deal with mediastinal emphysema and pneumothorax after tracheotomy, and many of Dr. Champneys' conclusions possess the greatest value alike for the surgeon and the physician. Thus, having shown that mediastinal emphysema may in a certain number of cases follow upon tracheotomy, he proves that pneumothorax results from this through rupture of the mediastinal tissues and escape of air into the pleural cavity. Since the air passes *beneath* the deep cervical fascia, separation of that structure or its division low down favours emphysema, as does bungling in attempting to introduce the tube, whereby the cellular spaces are opened up. The production of mediastinal emphysema is an ever-present danger in tracheotomy, and efforts at artificial respiration are very liable to induce it unless the utmost skill and attention are used to avoid the accident. Expiratory cervical emphysema is also fully dealt with and carefully con-

Digitized by Google

trasted with mediastinal emphysema, and the widely different modes of their origin demonstrated. The importance of the pathology of this latter condition has led Dr. Champneys into a most valuable research, and he has arrived at facts of the utmost interest, but upon which we have not space to enter. The concluding portion of the work deals with various practical points occurring in attempts at artificial respiration in the still-born, and apparently dead after tracheotomy, and is far from being the least important. In reviewing this work, we cannot speak too warmly of the skill evinced in planning the experiments and the accurate deduction practised in formulating conclusions. It marks a distinct advance in our knowledge both in pathology and of the details of methods for efficient pulmonary ventilation.

Sprains: their Consequences and Treatment. By C. W. MANSELL MOULLIN, M.A., M.D. Oxon., F.R.C.S. Eng., Assistant Surgeon and Senior Demonstrator of Anatomy at the London Hospital; formerly Radcliffe Travelling Fellow and Fellow of Pembroke College, Oxford. London: H. K. Lewis. 1887.

IN this little work Mr. Mansell Moullin deals with a subject of great importance, and one that deserves far more attention than it generally receives. The term "sprain" is of vague significance, and is used to denote a group of injuries varying widely in their severity and in the structure involved. A "sprain" may be so slight as almost to escape observation, and so severe as to imperil a limb. It may involve any part of the joint proper, or implicate also muscles, tendons, and vessels. But the subject derives still further importance from the gravity of the late results of apparently trivial sprains, and also from a general laxity in treatment. "It's only a sprain" is often heard as an assurance that the injury is not serious, and that its treatment is not difficult or urgent. The author clearly shows the error in this teaching, and, if for no other reason, his book is very acceptable. The various injuries grouped together under the head of "sprains" are described, and their appropriate treatment is detailed. This is carefully, simply, and well done, and the reader of this book must lay it down with a sense of a truer and higher appreciation of the importance of "sprains," both for diagnosis and treatment, and of the questions connected with their diagnosis. Mr. Moullin writes in an easy style, and but a very slight effort is required to follow him. In some places he seems to us to have written as if for men entirely ignorant of human anatomy. This no doubt was an oversight. So far as we have seen, the practice recommended by him is quite safe, and is the best known at present.

On the Growth of the Recruit and Young Soldier, with a view to a judicious selection of "Growing Lads" for the Army, and a regulated system of Training for Recruits. By Sir WILLIAM AITKEN, M.D., F.R.S. Second Edition. Pp. 259. London: Macmillan and Co. 1887.

ALTHOUGH this is professedly a second edition of the *brochure* bearing the same title published by the author in 1862, it is in reality a new and more comprehensive work. During the twenty-five years which have since elapsed important changes have been made in the organisation of the army, which have involved the necessity of enlisting annually more than double the number of recruits required under the previous system. To meet this increased demand it became imperative to lower the standard of height, and as it is impossible to obtain evidence of the age of the recruits who present themselves, this reduction involved the possibility of lads under eighteen years of age enlisting unless some check were introduced. With a view to minimise, as far as possible, the chance of the enlistment of lads unequal to the amount of work required from recruits, the responsibility of ascertaining the height of the candidates was transferred from the recruiting officer to the inspecting surgeon, and specific instructions were laid down as to the minimum chest-girth and weight of those who were to be deemed fit for service. One of the objects of the present volume is to assist the medical officer "to decide the apparent age by comparing the height with the weight, chest-girth and general physical development and growth of the recruit, recognising his antecedents in relation to modifying influences, especially in the search of 'staying power,' of healthfulness of constitution generally, and freedom from disease." This object the author has endeavoured to carry out, and in our opinion very successfully, by a careful examination and statement of "the physical equivalents" which may indicate the age and physique of the recruit, and the influence of certain modifying agencies upon development and growth. He has gone at considerable length into the question of the progressively gradual development of the recruit and young soldier as regards the osseous system and the vital organs which it encloses or protects, and has included in his work a number of valuable tables illustrative of the different points of which he treats. The appendix contains the existing regulations as to age, height, weight, and chest measurement of recruits for the Army and Militia, and extracts from the regulations of the Army Medical Department relative to the examination of recruits. The book is one which deserves the careful study of army medical officers in view of the increased responsibility thrown upon them by the changes in the organisation of the army, and in the mode in which the recruiting service is now conducted. We would also recommend it to the attention of all civilian medical practitioners who may be called upon to perform the duty of inspecting recruits. It is much to be desired that the results of the examinations by the latter were more in accord with those of the army medical officer than the statistics of recruiting show them to be, and this would be very much promoted by a study of Sir W. Aitken's work. It has a good table of contents, and a carefully prepared index. We would suggest, in any future issue that may be called for, the addition of a list of the various tables scattered through the work; this would greatly facilitate reference to information in a condensed form, which might be desired for immediate use by medical officers in the discharge of the duty of examination.

Manual of the Vaccination Law. By a BARRISTER-AT-LAW. London: Shaw and Sons. 1887.

MANUALS on this subject had all got out of date, and some were so ill-arranged that they lacked the simplicity needed for purposes of reference. Messrs. Shaws' manual is free from all these objections; and its introduction alone will make it a very helpful work to public vaccinators and vaccination officers, who, besides having to administer the law in certain respects, have also at times to convince the public of the true value of vaccination. This introduction, which covers some fifty pages, and is compiled by the editor, consists of a short history of vaccination and of the law relating to it; it gives ample evidence to show how the death-rate from small-pox has been diminished by reason of vaccination; it sets forth the grounds on which it is so necessary that vaccination should be performed with the highest degree of efficiency possible; it enters into the reasons which make revaccination so desirable; it explains the circumstances under which vaccination may produce injury; and it deals, amongst other things, with the relative merits of animal and humanised lymph: the several points discussed being supported by means of cases quoted and statistical evidence. In the body of the little work the several clauses of the Acts relating to vaccination are well and usefully annotated, and the several orders as to vaccination, including the New Instructions to Public Vaccinators, are set forth. It is unquestionably the best and most

Digitized by Google

useful manual on the subject, and it is clear that its anonymous editor is fully conversant with every detail connected with the administration of the vaccination laws.

Diaries.—We have received further specimens of these useful volumes. Blackwood's Diaries are published in over forty different sizes, and include most convenient descriptions for the office or pocket, at low prices. Charles Letts's series embraces upwards of eighty varieties, and contains an abundance of information which is practically in daily demand. The specimens before us from both these publishers are excellent, and can be cordially recommended to intending purchasers of such books.

SOCIETY FOR THE STUDY OF INEBRIETY.

AN address on the "Effects of Moderate Drinking on the Human Constitution" was delivered at the rooms of the Medical Society of London, on Nov. 23rd, by Dr. George Harley, F.R.S., who began by saying that he thought it might not inaptly be called one of the most burning questions of the day, seeing that the question of temperance is being at present hotly discussed, not only from a social and a medical, but from an individual and a national point of view. And notwithstanding that the majority of men are moderate drinkers—and consequently most patients belong to this class,—very little is as yet known of the effect on the system of small quantities of stimulants, although the effects of large quantities are familiar to all. The great difficulty the profession has in ascertaining exactly what are the real effects of small quantities of alcohol on the constitution arises from the following factors:—1. In no instance are the direct deleterious effects of moderate drinking sufficiently marked to necessitate any special form of treatment in a public institution. 2. Its deleterious influence on the bodily functions are so insidious as often to be attributed to entirely different causes. 3. The effects of moderate drinking manifest themselves in such a variety of different shapes that no single practitioner sees a sufficiency of any one of them to be able to draw reliable conclusions from them. 4. It is only men specially engaged in the treatment of liver, kidney, and brain diseases who come across the severer forms of functional derangements directly traceable to the effects of a moderate indulgence in alcoholic beverages. 5. In addition to which the matter is further complicated by the fact that several collateral problems require to be solved before even the threshold of the inquiry can be passed. Dr. Harley treated the various points in the following order:—The visible, the chemical, the physiological, the pathological, the therapeutical, and, lastly, the dietetical effects of stimulants upon the system.

Firstly: He began by pointing out that the visible and immediate effects of alcohol on the bodily functions, when it is taken in a quantity beyond what the system can tolerate, are those of cerebro-spinal paralysis, as it suppresses every function of the brain, cerebellum, and spinal cord. On the other hand, when taken in moderate quantity its primary effect is that of a cardiac and cerebral stimulant, the cardiac stimulating effect being apparent by the quickening of the pulse and the retinal congestion, while the brain stimulating effect is noticed in the volubility of speech and the restlessness of manner. The primary effect is, however, rapidly followed by the supervention of its paralysing action, as is seen by the special senses of feeling, tasting, hearing, smelling, and seeing becoming obtuse, on account of the impending paralysis of the sensory nerves, the speech becoming thick and the gait unsteady. From a similar incipient paralysis of the motor nerves, coupled with a loss of the coördinating power of the cerebellum. The intellectual faculties likewise exhibit the paralysing action by a diminution of mental grasp, associated with a tottering of the moral control. Even the sympathetic nervous system is not exempt from the paralysing power of alcohol, as is seen, firstly, by the flushed and heated face, and, secondly, by the subsequent cold, clammy, pallid cheek.

Secondly: This action of alcohol on the nervous system Dr. Harley said he believed was entirely due to its peculiar chemical action on blood-nerve-pabulum. Quoting a number of experiments, showing that even such a small amount of alcohol as 5 per cent. completely deranged the functions of the blood, more particularly its power of absorbing oxygen and exhaling carbonic acid, and seeing that every function of organic life is intimately connected with oxidation (for in exact proportion as it is accelerated or retarded are the main functions of the body accelerated or retarded), this asphyxiant action on the blood-nerve-pabulum, he thought, was amply sufficient to account for the gradually obtusing, and ultimately completely paralysing, action of the alcohol on the nervous system.

Thirdly: Dr. Harley next considered the extraordinary effects alcohol in small quantities produces when directly conveyed to the liver through the portal circulation, citing in illustration the experiments of himself and Bernard (who followed him in this respect) on the artificial production of diabetes in animals by the injection of from 10 to 16 centimetres of alcohol and water into the mesenteric branches of the portal vein, and adducing this as an explanation of—

Fourthly: The effects of nipping (not actual drunkenness), as shown by the tables of comparative mortality in the Registrar-General's reports, which conclusively demonstrate that those given to nipping have a six times greater mortality from liver diseases than others, and that the kidneys, heart, and brain are the next three organs which so-called small indulgences in alcoholic drinks cause to become diseased.

Fifthly: From this part of the subject the lecturer passed on to the consideration of the pernicious effects of over-stimulating in cases of dangerous diseases, and pointed out the great difference between the merely stimulating effects of spirits, in the shape of brandy, whisky, gin, and rum, as compared with the nutritive as well as stimulating action of wines and beers in the treatment of exhausting diseases. The use of the latter in all cases where the exhausted patient could take little nourishment he recommended as strongly as he condemned the use of the former in the graver forms of exhausting disease.

After specifying *seriatim* the therapeutical actions of alcohol when taken in different quantities in various diseased states, Dr. Harley turned to the question: Is alcohol a food? To which he replied that although alcohol could not be regarded as a food in the same light as bread and beef, yet in so far as it had the power of indirectly aiding in the sustaining of vital phenomena, more particularly by assisting in the digestion and assimilation of other foods when taken into the stomach in small quantity, he considered it had a legitimate claim to be ranked as a supporter of animal life. Finally, he wound up by saying that, although he was a strong advocate for temperance, he approved of the present social habit of taking wine at dinner parties, for he believed that when taken in strict moderation it was conducive alike to happiness and health, as it made one feel not only contented with oneself, but pleased with one's companions, and consequently materially contributed to one's personal comfort; for, as everyone knows, good spirits are promoters of digestion, as well as whetters of the appetite, while ill-humour is exactly the reverse.

The second of a series of two lectures was delivered by Dr. Norman Kerr on Nov. 30th, in the large room of the Medical Society of London. The subject was "The Different Forms which Inebriety may assume." The lecturer began by defining inebriety or narcomania as a disease of the nervous system, characterised by a very strong morbid impulse to, or craving for, intoxication. When developed, it appeared in varied guise. These forms were first divided into two general groups, periodical and constant inebriety. Of 103 admissions to the Dalrymple Home, 45 were of periodic inebriates. American experience was similar. Among females functional periodical inebriety was the most common; functional perturbation at the various crises of puberty, parturition, lactation, and the menopause being a prolific cause. There were also many varieties of male inebriate periodicity. There were regular and irregular periodicities. Cases were cited illustrative of chronological, weekly, fortnightly, lunar, and other periodic inebriate outbreaks; as well as of the periodicities of occasion, commercial and climatological forms. Among the cases of constant inebriety referred to were those of medical men, clergymen,

Digitized by Google

literary and scientific workers, and Christian visitors. Both periodic and habitual inebriates could be classed under two other heads. Inebriety might be social or solitary; some never drink except in "good companie," or they indulge only when alone. The disease of inebriety at times assumed a form determined by some complicatory disorder. There was in this way the inebriety of insanity, as of syphilis, of heat apoplexy, of operations, &c. An extensive group of forms was that where the particular form was correspondent to the particular inebriating agent. Though in many cases the disease existed prior to the manifestation of inebriate symptoms or to consumption of any intoxicant, the subject of the disease loathing the potion itself, the characteristic narcotic and anæsthetic properties of the different inebriants gave a variety of forms of the morbid affection. Alcoholic inebriety was first considered, with its modification by idiosyncrasy, by the strength of the intoxicating principle, by the kind of alcohol, as well as by the variety of beverage. The lecturer here pointed out the varying properties of the heavier and lighter alcohols, the recent outbreak of methylated spirit inebriety, the differences between wine, champagne, beer, and spirituous inebriety, the special features of absinthe intoxication, of cider inebriation, of kava, and other forms. Intercurrent affections of alcoholomania introduced delirium tremens, mania a potu, alcoholic epileptic mania, fatal and non-fatal alcoholic poisoning, chronic alcoholism, alcoholic dementia, alcoholic multiple neuritis, &c. Opium inebriety differed from alcohol inebriety, in being a functional disease without the marked organic lesions observed in the latter, in being a solitary, unsocial habit. in being more continuously indulged in, in being less persistent among females, and, though less perverting to the *morale*, in being more difficult of cure. Opium soothes, alcohol maddens; opium raises, alcohol lowers, temperature. Enormous quantities of opium were taken. Chloral inebriety was increasing alarmingly, was unsocial, and generally associated with alcohol. This was a disease of function, and was affected by both sexes. Chloral, like alcohol, reduced temperature. Chlorodynomania was also spreading; one patient had taken an ounce a day for six years; three and four ounces had also been taken daily. Generally occurring in females, chloroform and ether inebriety were contrasted. Both were increasing. The chloroformaniac led a life of alternate woe and bliss till it crystallised into a protracted misery, was very fatal, and was usually solitary. Etheromania was less terrifying and less fatal, but as imperious. The lecturer narrated cases in London practice, and described the ether intoxication in the north of Ireland. Gelseminum and cocaine inebriety were touched upon, and Dr. Kerr concluded by considering the question, "Is there a true tobacco inebriety?" to which he replied in the negative.

PROVIDENT DISPENSARIES.

A PUBLIC MEETING was held on the 6th inst. at the Society of Arts, under the presidency of Sir T. Spencer Wells, to consider the report of the Medical Attendance Organisation Committee appointed at a conference held about twelve months ago at the same place. This committee, consisting of medical and lay members, recommended a comprehensive scheme of medical attendance for the industrial classes in the metropolis on a self-supporting basis, involving the creation of dispensaries in each district, these dispensaries to form a union with the hospitals. The proposed subscriptions were sixpence a month each for single persons, a shilling a month for a man and wife without children, tenpence a month for a man and wife with children, and threepence a month each for children under sixteen years of age. These institutions, it was suggested, should be available only to persons who could declare that their earnings did not exceed the following rates: For a single person, or a man and wife, an average of 30s. a week; for a family, 40s. a week; and for domestic servants, £15 a year. Persons requiring immediate attendance should pay an entrance fee of not less than half-a-crown, which should entitle them to treatment for one week, after which, if they should continue ill, they should pay not less than a shilling a week if able to call upon the doctor, and not less than half-a-crown a week if visited at home. This higher rate was deemed necessary in order that the dispensaries might retain their strictly provident character. In the opinion of the committee, the indiscriminate manner in which the public are admitted to the out-patient departments of hospitals inflicted great injury on a large number of ordinary medical practitioners, and tended to pauperise the applicants, and to waste the time of the medical staff of the hospitals.

Sir Spencer Wells, in opening the proceedings, warmly advocated the proposed scheme, as calculated to engender habits of prudence and self-reliance in the poorer classes. No doubt the payments were small, but he believed the medical profession did not realise how large they might become in the aggregate.

Mr. Timothy Holmes moved the first resolution, which was as follows:—"That the scheme of the Medical Attendance Organisation Committee for the regulation of provident dispensaries be accepted by this conference as worthy of the support of the working classes of the metropolis, and as offering an equitable basis for the co-operation of the medical profession." He said that any scheme must be necessarily somewhat of a compromise. It was more difficult to deal satisfactorily with this question in London than in country towns, because in the metropolis they were trammelled by the fact that the poor were not only invited but solicited to accept gratuitous medical relief from institutions with which the best-known names in medical science in the country were connected, and the poorer classes could not therefore be made to see at first sight why they should pay for that which could be got for nothing. Therefore the second part of the report as to the means by which provident dispensaries could be connected with the hospitals was of urgent importance. The scale of fees was exceedingly moderate, and one which ought to be within the reach of all poor persons who were not paupers. The only doubt in his mind was whether the scale was sufficient for the wants of the medical practitioner. Another matter upon which the framers of the scheme were very much exercised was the possibility of excluding persons beyond a reasonable scale of earnings from the benefits of the scheme. It was very easy to name a figure of limitation, but in practice it gave rise to very great hardship. The active co-operation of the medical profession was absolutely necessary for the working of the scheme.

Dr. J. Grey Glover, in seconding the motion, said his only doubt was whether the fees were adequate. When they saw handbills issued offering medical attendance for 6*d.* a visit or 1*s.* per week, or the announcement of a children's medical fund at a grocer's shop, it was time something was done to maintain the dignity of the profession. (Cheers.) The hospitals had a splendid chance of increasing their usefulness by co-operating with the promoters of the scheme.

Mr. J. P. Hentsch proposed, and Dr. Paramore seconded, an amendment declaring that, whilst a check ought to be put on the present system of indiscriminate out-door relief, it would not be advisable to adopt the scheme submitted by the committee.

A discussion, in which Mr. R. H. S. Carpenter, Mr. A. P. Hills, and others took part, followed, and the amendment was shortly afterwards put to the meeting and negatived, the original motion being carried by an overwhelming majority.

On the motion of Mr. W. Bousfield, seconded by Dr. Gilbart Smith, it was afterwards agreed to approve of the co-operation of hospitals with provident dispensaries.

The proceedings then terminated.

THE HOSPITAL SUNDAY FUND.—Of the £37,525 which the Hospital Sunday Fund Committee of Distribution recommend be awarded to the 101 hospitals, 7 institutions, and 50 dispensaries, the following are the sums apportioned to the twenty-one London general hospitals hereinafter named:—Charing-cross, £939 11*s.* 8*d.*; French, £208 6*s.* 8*d.*; German, £677 1*s.* 8*d.*; Great Northern Central, £270 16*s.* 8*d.*; Italian, £67 14*s.* 2*d.*; King's College, £1354 3*s.* 4*d.*; London, £3333 6*s.* 8*d.*; Metropolitan, £208 6*s.* 8*d.*; Miller Hospital and Royal Kent Dispensary, £260 8*s.* 4*d.*; North-West London, £260 8*s.* 4*d.*, Poplar, £239 11*s.* 8*d.*; Royal Free Hospital, £885 8*s.* 4*d.*; St. George's, £1875; St. John and St. Elizabeth, £145 16*s.* 8*d.*; St. Mary's, £1822 18*s.* 4*d.*; Seamen's, Greenwich, £572 8*s.* 4*d.*; Middlesex, £1979 3*s.* 4*d.*; Tottenham Training Hospital, £281 5*s.*; University College, £1510 8*s.* 4*d.*; West London, £520 10*s.* 8*d.*; and Westminster, £937 10*s.*

THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1887.

WE announced last week that the petition praying for a Charter under the style of "The Senate of Physicians and Surgeons," with power to grant degrees in Medicine and Surgery, had been presented to the QUEEN in Council by the Royal College of Physicians of London and the Royal College of Surgeons of England, and that this petition will be considered by a committee of the Privy Council on the 16th of January in next year. It is doubtless because of the delay in forwarding these documents, which were laid before the Royal Colleges in July last, when the delegates were empowered to carry them into effect, that the consideration of the scheme proposed by University and King's Colleges has not yet been considered. The question of the formation of a university with faculties in other subjects is so intimately connected with the power of granting degrees in a medical faculty only that the schemes could only be taken together, and we hope that no time will now be lost in deciding on the two proposals. The petition and draft Charter now presented are exactly the same as the copies printed by us on July 2nd, and their clauses were thus summarised by us in our editorial columns of that date:—

"The delegates of the Royal Colleges have also submitted for approval drafts of a petition and Charter, and these, having also been passed by the Fellows of the College of Physicians and the Council of the College of Surgeons, will at once be laid before the Queen in Council. By the Charter, which is published in another column, power is sought to form a governing body of forty-eight persons—twenty-four from each College—to be called the Senate of Physicians and Surgeons, to whom shall be entrusted the framing of the necessary regulations and the authority to see that such regulations are complied with. The Council of the College of Surgeons is composed of twenty-four members, and these will, as elected, become the representatives of that College on the Senate, whilst twenty-four Fellows of the College of Physicians are to be chosen, three of them to go out of office annually, but to be eligible for re-election. We cannot but think that this eligibility for re-election is a mistake, for it will allow only a minimum of change, and the Senate will practically become a permanent body, devoid of a sufficient number of young members to enable it to readily adapt itself to changes in teaching and examination. An error similar to that committed by the founders of the University of London should have been avoided. The President of the Senate will hold office for two years, and will be in succession the President of the College of Physicians and of Surgeons respectively, whilst two Vice-Presidents will be elected annually from among the members of the Senate. Twelve members are necessary to form a quorum, and the vote of the majority present is to be decisive. The degrees in Medicine and Surgery are to be conferred on any person who, 'by passing the examinations formerly held by both of the Colleges separately, or by passing the examination held by the Examining Board of the two Colleges, or by passing any other examination to be held by the two Colleges jointly or separately, has already acquired or may hereafter acquire, the qualifications for registration under the Medical Act, and who shall have also complied with such further regulations (if any), or undergone such further examination (if any), as the Senate may from time to time see fit to impose or require.' The past Licentiates of the College of Physicians and Members of the College of Surgeons will by this clause be placed on exactly the same footing as those who qualify in the future, and this just and far-reaching provision will secure a wide amount of sympathy among the members of the profession in favour of the movement. The questions of an additional examination or examinations and of a title are left open for future discussion, and are therefore omitted from the Charter.'

It will be noticed that the term "University" is omitted from both the petition and the draft Charter, but this is scarcely likely to disarm any proposed opposition, for the power of granting degrees has hitherto exclusively belonged to a body with this title. As time has passed on, the objections to a one-faculty University have steadily increased, for the scheme of the two Colleges is opposed by most of the Universities, who demur to this power being granted to corporations; by the Colleges of Surgeons and Physicians in Scotland and Ireland, who desire similar power if it be granted to the London Colleges; by the provincial medical schools, who object to London medical students having degrees conferred on them, with a compulsory term of residence as a condition; and by the Society of Apothecaries, whose diplomates are left out in the cold. These objections will all be presented to Her Majesty in Council before the date fixed for the consideration of the petition. The petition and charter of University and King's Colleges, which have practically received the support of the Association for promoting a Teaching University in London, were printed by us on August 6th, so that the two schemes can be compared by those who take interest in these important educational movements. The University of London has entered a *caveat* against the formation of a new University in London, although its proposed functions and objects are so entirely different from those now discharged by the existing institution, and its statement has also been laid before the Privy Council. This action of the Senate received the support of the majority of the members of a combined committee of the Annual Committee and of the Special Committee on the Constitution of the University on November 25th, and the question will be brought before Convocation at their next meeting in January. It is curious and interesting to note that the University of London alone protests against the formation of a University by the two great teaching institutions in London, whilst all other Universities except London object to the two Royal Colleges of Physicians and Surgeons being empowered to grant degrees. We shall return next week to the Statement which has been forwarded from the Senate of the University of London to the Privy Council and which, together with a petition from the Association of General Practitioners, we print on pages 1186 and 1187.

FORTY years ago CHARLES KINGSLEY told the story of the tailor's life—told of all the degradation and misery which resulted from the employment of middlemen who intervened between the master tailor and his men. Thirty years before, this system was unknown. Masters who received orders employed the working tailors directly, and the work was done in the master's house and reasonable wages were paid. But the times altered, Government

Digitized by Google

contracts were let to the lowest bidder, and the system of cutting down prices led to the employment of the middleman, often not a tailor himself, whose sole occupation was to let the work to someone else, and to live upon the profits for which he did not labour. When KINGSLEY wrote his Parson Lot tract on "Cheap Clothes and Nasty," the slang of the trade had already divided the shops into two groups, the "honourable" and "dishonourable," the former employing men on the premises at fair wages, the latter giving men the work to take home at the smallest possible remuneration. But worse than this, the work was not given to them directly, but to a "sweater," so that the profit was divided not between the master and the men, but, to use KINGSLEY'S words, "the sweater and perhaps the sweater's sweater, and a third, and a fourth, and a fifth," had their share of it. Even at this time the honourable shops in the West-end were but sixty, while the dishonourable numbered four hundred and more; while at the East-end the honourable shops were unknown. Ground down by this system, the conditions under which the working tailors lived were heart-rending to a degree; sleeping together, working together in ill-ventilated rooms, working from early morning till late at night, and often through the night, they readily fell a prey to disease, phthisis especially attacking the breathers of the vitiated air in which they lived. Even the paltry wages which they received were taxed to pay usurious rent and high rates of food, which the sweater supplied. The moral and physical degradation was clearly proved; separate public meetings were held of working tailors employed both in the honourable and dishonourable trades, and the appearance of the attendants at these meeetings showed but too plainly to which branch they belonged. The publicity given to the facts to which we have referred aroused considerable interest, the subject was discussed in pamphlets and in newspapers, and at last there seemed some prospect that the system under which human beings starved would be so far modified that Alton Locke and his associates would be numbered with the past.

Forty years ago! And what has happened since? The condition of the working-classes generally has improved, the necessaries of life have become cheaper, the Factory and Workshops Acts have been directed towards the limitation of the hours of labour for women and young people employed in these places, but the sweating system has continued, and the account given by KINGSLEY of the tailors' sufferings is as true now as it was when he wrote the history of Alton Locke.

It is little more than three years since our Commissioner instituted an inquiry among the tailors in the East-end of London, and visited their homes and workshops. He found the "sweater's den" ill-ventilated, over-crowded, and dilapidated; the requirements of the Factory Acts rarely complied with; the inspector's visits rendered useless, for "on the appearance of any stranger the women are often distributed about the private parts of the house—in the bedrooms, kitchens, and so forth. If any question is asked, there is always a ready reply: the one is a niece, the other is a daughter; and if they are working, it is only for the family, and not in the pursuit of their trade." The unfortunate worker, we were told, greedily accepts starvation wages, and even assists his employer to defy the laws instituted to protect him, fearing that by availing himself of our Legislature he may lose the little he is able to earn. Even in factories where the law is complied with, the women are only paid for three-quarters of the day, and if a woman wishes to earn a full day's wage she must work from eight in the morning till eleven or twelve at night. The evils which KINGSLEY described had even become accentuated owing to the immigration of foreigners, mostly of Polish Jews, whose only means of existence was the learning this ill-paid trade.

There is now presented to Parliament the report of Mr. J. BURNETT, the labour correspondent of the Board of Trade, whose duty it was to inquire into the sweating system at the East-end of London, and as the result of his labours the public are enabled to learn the cause of the increasing misery which seems inseparable from the tailor's trade. The demand for cheap clothing has not only reduced the remuneration of the tailor, but has led to a minute subdivision of work, so that we have "cutters, basters, machinists, pressers, fellers, button-hole workers, and general workers all brought to bear upon the construction of a coat," so that the workman who was formerly competent to make the whole garment is replaced by others whose knowledge only extends to a portion, and thus numbers of persons come to be employed who are only required to contribute to a small fraction of the whole. The less complete knowledge that is needed is easily acquired by the foreign immigrant, and as the result thousands of Polish and German Jews have entered into competition with the English tailor, and the sweater is able to sublet his work to these unfortunates at almost nominal wages. The inspectors of factories and workshops have doubtless done their best, but they are obviously unable to control the conditions of work in the numberless places in which it is carried on.

The report teems with evidence that the workers are paid at rates which are insufficient to maintain life for any lengthened period. For a woman to be unable to earn more than seven or eight shillings a week when in work is a common event; thus, a female trouser finisher, who is mentioned, receives "fourpence per pair for large, thick trousers, which she gets from a woman in the same house, who herself gets them from a sub-contractor. She could make six or seven shillings a week at this work." The price for making children's suits, except a little braiding done after the work is sent back, ranges from threepence to elevenpence, with cotton to find. Button-hole workers often get but a halfpenny per hole. The hours of work are dependent upon the requirements of the trade, often lasting from six in the morning until midnight; and one woman told the story how, when the inspector came after hours to a Jew's workshop, she was sent out into the yard and the gas turned out, but that after he had left she was obliged to work two hours longer. For the operative to complain of these conditions is to lose his work; there are but too many others who are glad to obtain it.

The remedies to which Mr. BURNETT directs attention are, mainly, the increased control of the hours of labour and the application of the Factory Acts to men as well as to women, the restriction of the immigration of foreigners, the elimination of the sweating system for work done

Digitized by Google

under Government contract, and finally the strict enforcement of the Factory and Public Health Acts. The subject is urgently pressing, and the public must bestir themselves to terminate an evil that has become intolerable. Much might undoubtedly be done if right-minded persons refused to give their custom to any but master tailors who employed directly their own workpeople without the intervention of the sweater, and who provided suitable workshops in which the trade could be carried on. For those whom no other consideration will move, they may well think of the risk of infection to which they are exposed by wearing clothes made under conditions which are absolutely incompatible with health; it is the daily experience of London health officers to find fever and small-pox prevalent in rooms in which the tailor works, and none can tell how many of the unexplained cases of contagious maladies among the rich may not be due to these overcrowded and unhealthy tenements. But whether feelings of philanthropy or fear are to exercise an influence, it is surely time that some strenuous effort was made to terminate circumstances that are a disgrace to our civilisation.

WE appear now to have come to the termination of the fourth year of the European cholera prevalence of 1884-87, and during the year now drawing to a close the epidemic has been much more circumscribed and much less fatal than during either of the three previous years. Apart from a slight recrudescence of cholera in Austria-Hungary early in 1887, the disease has been limited in its manifestations to the southern half of Italy, including the island of Sicily, and to Malta.

The first outbreak that was notified in Southern Europe was the occurrence of a few isolated cases and deaths in the province of Catania, in Sicily, in March last. From that date until July no further intelligence was received, but in the latter month the disease became widely prevalent in the same province, and it extended to several of the neighbouring provinces of the island—namely, those of Girgenti, Syracuse, Catania, and Messina. The southern coast of the mainland also became infected, the disease being as yet limited to the province of Calabria. In all, over 200 fatal attacks occurred in Italy during that month. With the month of August there was a considerable extension of the disease in Sicily, the provinces suffering most being those of Catania, Messina, and Palermo, a large number of inland towns and villages being also attacked. On the mainland the most important extension during August was to Naples and certain places along the gulf, the total record for the disease during the month in Italy being over 700 deaths. But during August Malta also became invaded, and, the disease spreading somewhat rapidly inland to the villages occupied by the natives, as many as 128 deaths occurred. With the month of September a very serious exacerbation of the disease occurred in Sicily, the towns of Palermo and Messina and the province of Catania being principally involved. In Messina alone there were nearly 1900 attacks and over 800 deaths. On the mainland there was also a substantial increase in the fatality. The disease still clung, in the main, to Naples and such places as Pozzuoli and Castellamare in the neighbouring gulf; but there was also some recrudescence in the southern part of Calabria, and notably near Cape Colonne, and a few fatal attacks were reported from Rome. In all, no less than 1500 cholera deaths were publicly notified. In Malta the disease was still steadily maintained, and before the end of the month 141 additional cholera deaths had been registered.

With the month of October there came a decided diminution of the epidemic in Sicily; the outbreak was all but confined to the town of Messina, and the total death-roll for the month fell to fifty-eight. And at the same time no fresh intelligence as to cholera was received from the mainland. But in Malta the epidemic was maintained with much the same severity as had characterised its spread and fatality during the two preceding months, and between 140 and 150 more cholera deaths took place. The month of November brought the epidemic to a close. No fresh cases were reported either from Sicily or from the Italian mainland; by the middle of November intelligence of fifteen additional cholera deaths had arrived in Malta, after which all further news ceased. The total mortality from cholera during the year in Italy, including Sicily, was somewhat over 2200; and in Malta it was 429. This result stands in contrast to a fatality in Italy of 14,299 in 1884, of 3469 in 1885, and of at least 6244 in 1886.

The epidemic has again been replete with lessons teaching the great power of efficient sanitation as the only trustworthy means of combating the disease. Rome, with its unpolluted water services, has again stood the test of imported infection; the incidence of the disease in Naples has been but trivial when compared with that which marked the year 1884, before the city was provided with a proper water supply; and the abandonment by Italy of the system of quarantine by land, and to a large extent by sea, has also been associated with a diminished amount of cholera. On the other hand, Malta, always one of the foremost in imposing stringent quarantine regulations, has found these to fail her; whereas the influence of proper sanitary measures has been shown by the striking immunity from the disease of the garrison, who have clean and decent lodgment, and by the limitation of the epidemic to the worst and most insanitary localities occupied by a native population, who, instead of cleansing their villages and their houses, have been led to trust in the quarantine restrictions imposed by their Government. The lesson thus taught ought not to be thrown away; and it is to be hoped that it may lead to a reconsideration by the Colonial Office of the attitude they hold with regard to this question, in advising the Home Government to give their sanction to a local law which brings about such serious results. Our Government have now refused to allow a troop-ship to be put in quarantine off Suez, and they have thus dealt a first blow at the Egyptian regulations; the same policy should be followed as regards the retrograde measures adopted in our little Mediterranean colony.

In the United Kingdom we have for a fourth year succeeded in preventing cholera from effecting an entrance in our midst, by means of reasonable measures of precaution at our ports, and by the aid of the great impetus to increased sanitary supervision which was brought about by the knowledge of the danger, and by the results of the Government Cholera Survey in so many parts of England and Wales. All vessels coming from infected ports have been

Digitized by Google

dealt with by the medical inspection system; means of isolation have been very generally in readiness in case of need; and in no instance has any anxiety occurred, and this notwithstanding the fact that we are, by means of our commerce and otherwise, brought into such constant communication with the countries which, both in Europe and in the East, have been affected with cholera. The past should inspire confidence in our system of prevention, and, having regard to its value in connexion with many other diseases than cholera, it should act as an incentive to us to continue to carry out its principles without relaxation.

AT a time when science is endeavouring to provide for death by sleep for the lower creation, it is not too much to hope that something of the same kind may be provided for man. Dr. B. W. RICHARDSON, the inventor of the lethal chamber which has been erected at Battersea for the painless extinction of the life of the friend of man, the dog, said in his lecture on Euthanasia for the Lower Creation, delivered before the Society of Arts, in which the details of the lethal chamber were described, "that man could never hope to secure for himself so painless and happy a death as had thus come through the hand of science to the lower animal kingdom." And, indeed, the difficulties surrounding the question whether the death of man can always be rendered painless are so great that for the present they seem irremovable. Mr. WILLIAMS, in his work on Euthanasia, published some twenty years ago, argued in favour of the idea. He urged that man ought, as a being having free will and judgment, to claim the right, when death was inevitable, to have the act of death made painless. Mr. WILLIAMS was, if we remember correctly, a schoolmaster by profession, and, although a very able and observant man, had not the practical knowledge of the subject to enable him to work it out in such a manner as to carry conviction of sufficient quality to institute a practice.

The author of "The Right to Die" strikes out somewhat in the same lines, but he also does not appreciate what are the obstacles, moral and legal, against any organised method for conferring on the human subject the boon of a painless death. All lay writers who handle this subject turn to the profession of medicine to settle the difficulty. The doctors are to be the men to give the *coup de grâce* to writhing, or flickering, or hopeless men, women, and children in the throes or agonies of death, and the profession very wisely—nay, even humanely—withdraws from the proposition. The members of the profession feel that it is their duty to prolong life in a very large number of instances to the very last flicker. They sometimes see by this action life restored when all has seemed to be lost. They have, in fact, no correct measure of absolute death short of death itself; and there are cases where death seems actually to have taken place in which there is doubt whether an inappreciable spark of life may not remain and once more declare itself. Such facts as these have ever stood, and promise long to stand, athwart the practice of euthanasia *secundum artem* as a system, if the professors of medical science and art are to be the administrators.

There is, nevertheless, a divine and blessed art at the disposition of every medical man. If the physician or surgeon may not shorten life methodically even under the most pressing circumstances, he may shorten pain and make the inevitable death easy and tranquil. For this reason we rejoice to welcome the new work of Dr. MUNK on "Euthanasia, or the Medical Treatment in Aid of the Dying."[1] We have known Dr. MUNK long as one of our rare medical scholars, and have been always grateful to him for that Roll of the Royal College of Physicians which is sure to place his name on the roll of fame as one of the trusted and trusty writers of biographical history. But here he appears before us in a new light. He has looked up the authority of history to learn how far the physician may advance on the best authority of his profession towards treatment in aid of an easy death; he has added to what he has read that which he himself has observed, and has put into a nutshell the duties of the medical practitioner in regard to euthanasia, in a style as simple as it is classical. His suggestions for treatment are confined to the rules which, applied to the dying, enable the physician so far to make use of remedies of the true narcotic class—alcohol, opium, ether—and of antispasmodics like nitrite of amyl—to the extent of alleviating acute sufferings, and, without hastening death, of making the approach to death peaceable. To this extent medical art may go; no further. If it went further, it would be ever open, in its most innocent development, to the criticism of suspicious relatives and friends; while it might be made the cause of doubts which had a real meaning, and which would of a certainty give origin to many serious legal inquiries. In plain terms, euthanasia, beyond the position in which Dr. MUNK has so judiciously put it, is an impossibility unless the law is allowed to render its extension possible. The study of Dr. MUNK'S little treatise may, however, we foresee, reproduce discussion on a collateral, and to some minds very important, question. There are persons who contend that the law should be so changed that one stricken with a fatal disease—say, fatal malignant disease—might, on his own instance, guard by proper legal instrument everyone else from blame, and thereupon claim the benefit of euthanasia. In any proposed change of law for allowing this practice, the medical profession would undoubtedly have a powerful voice for or against. Yet if the law were changed the position of the profession would remain the same. There is no more reason that a representative of medicine should take part in the production of the euthanasia than anyone else. His diagnosis might determine the fact that the sufferer would die from disease. His evidence might be required to determine that death had taken place. But the State would have to determine the mode of death, and the manner in which it should be carried out. The State would have to appoint a legal administrator, or would permit the applicant for relief from life to take the cup, like SOCRATES, and, mocking ÆSCULAPIUS with all his tribe, wilfully seek his own dissolution.

THE problem of reforming the out-patient department of hospitals, and developing a healthy and creditable provident system of medical attendance on the wage-earning classes, still continues to exercise the minds of a large number of the profession. Twelve months ago, at a meeting held at the Society of Arts, a committee was appointed to report on the subject of assurance as applied to the treatment of the sick.

[1] Longmans and Co.

Digitized by Google

The meeting resolved that the future medical attendance on the poorer classes ought to be conducted on the principle of sick assurance, and that the attention of the governing bodies of hospitals and other public authorities be called to the necessity for some check on the indiscriminate provision of medical treatment at hospitals and dispensaries. The committee has been at work twelve months, and has elaborated a scheme which was discussed at a public meeting called for the purpose, on Tuesday, in the Society of Arts, and presided over by Sir SPENCER WELLS. The committee, for convenience, divided its work into two parts: 1. The preparation of a scheme for medical attendance on the industrial classes in the metropolis, to be self-supporting and acceptable to the medical profession 2. The consideration of the desirability of forming a union between the hospitals and dispensaries in each district of London. We shall first briefly describe the chief points of the scheme of attendance. (1) All members to be approved by the medical officer under whom they wish to be placed. (2) A registration fee of one shilling. (3) The rates of contribution to be: single person, 6*d.* per month; man and wife, not having children, 1*s.* per month; man and wife, having children, 10*d.* per month; each child under sixteen to pay 3*d.* per month, not charging for more than four in a family. Persons joining to declare that their average wages do not exceed 30*s.*, or that of the family 40*s.* per week; if domestic servants, their wages not to exceed £15 per annum. Special rules are suggested for persons requiring immediate attendance, and for persons who, on account of exceptional delicacy of health, cannot, with fairness to the medical officers, be admitted as provident members at ordinary rates. The scheme urges that each dispensary be "as far as possible" self-supporting, and that all the medical men in a district be invited to a conference with representatives of local general hospitals, and have power to elect a certain number of representatives on a provisional committee. The second part of the committee's work was a series of resolutions providing for friendly co-operation of hospitals with provident dispensaries, the object being to induce hospital authorities to relegate a large proportion of their out-patients to neighbouring provident dispensaries; to give patients of provident dispensaries with grave diseases and needing hospital treatment ready and certain means of obtaining it, for the mutual advantage of the hospital and of the patient; and finally providing for the use of the dispensaries, under certain restrictions, by students as a field for the study of common diseases.

Such are the principal features of the scheme, which represents a good deal of labour and trouble and a great many meetings on the part of the committee. It will be seen by the report of the meeting in another page that the scheme in its two parts was accepted by a large majority of the meeting, in spite of the opposition of a small minority. It is not pretended, of course, that the remuneration is adequate, though it is better than that of many schemes of private dispensary practice attended with every humiliation of advertisement and low charges, and as a working scheme for the metropolis, where so much gratuitous advice is to be had without adequate check on abuse. Besides, the rate of payment is not necessarily more than a suggestion for a *minimum* rate; it can be raised at any dispensary accordi
local committee. It is undenia
periodical payment suits many person
it easy to pay medical bills, and there
fact that the working classes in London have
out of the notion that they are to have a ph
medicine without payment. The scheme of the c
is on the lines of the best provident dispensaries. Th
a guinea midwifery fee; there is a strict wages limit,
the remuneration to the medical men is infinitely better than that of many co-operating medical societies. If the committee could bring the authorities of hospitals to a hearty acceptance of the part of the scheme which requires the co-operation of hospitals with provident dispensaries, they would do more for hospitals and provident dispensaries than all previous movements for establishing these institutions in the favour of the public.

IN spite of the abundance and nature of the evidence adduced of late years in support of the contention that pneumonia is to be regarded as a specific infectious disorder rather than a disease due to exposure, the argument is not all on one side. Dr. SEIBERT of New York has on more than one occasion forcibly drawn attention to the close relationship that prevails between the occurrence of pneumonia and certain meteorological states, of which the relative humidity of the air is foremost; and his contention has never been satisfactorily answered. A similar line of reasoning is adopted by Dr. BAKER, of Lansing, Michigan, who, in drawing his conclusions, has availed himself of the statistical method to so large an extent as almost to preclude those fallacies which beset the use of this method in its application to disease. In Michigan State there has prevailed for several years a system of registration or notification of disease, whereby returns are made every week by practitioners to the State Board of Health of cases of illness that have occurred in their practice; and by a comparison of such returns, together with the meteorological reports which are made daily in all parts of the State, Dr. BAKER has constructed curves of the monthly incidence of pneumonia as compared with the temperature variations, on the average of the past eight years. The result is a close correspondence in the occurrence of pneumonia and a falling temperature, the only difference being an almost uniform interval of one month between the two curves—i.e., the highest number of cases of pneumonia being reported a month later than the lowest recorded temperature. An almost precisely similar parallelism between the disease and the temperature was shown by Dr. BAKER to obtain in respect to the statistics of the United States army during the war, in the mortality from pneumonia in London during thirty years, and also in the prevalence of bronchitis in Michigan; so that from this enormous field it seems clearly to issue that there is a constant relationship between the disease and the temperature, and, consequently, with the absolute humidity of the air, which varies with the temperature. Granting this as proved, it still remains to explain how the condition of the air inhaled can cause pulmonary inflammation. The old and almost (up to within very recent times) universally accepted notion that pneumonia is caused by sudden changes

Digitized by Google

of temperature is not at first reconcilable with the fact that pneumonia prevails more in cold seasons, when such sudden atmospheric changes are less common than in warmer seasons; but it is quite consistent with the fact that in cold weather individuals are always exposed to great variations owing to the difference in temperature between the in-door and out-door atmosphere. Nevertheless, the ancient doctrine of "chill," even when explained by the light of modern physiology as operating through disturbance of the vaso-motor system, and thus producing local hyperæmia of one or other part of organ of the body, is not an adequate explanation. "Congestion" is one of those shibboleths, which are made to cover a great deal of ignorance. Even if local congestions do thus occur, between them and the inflammatory process there is a wide gulf. Hyperæmia may be a stage of inflammation, but inflammation is not the necessary consequence of hyperæmia. As regards pneumonia, it would seem that it is absolutely essential to seek for another factor in its causation over and above mere chilling of the surface and the resulting vaso-motor disturbance; and this factor has been sought in the introduction into the lung of some peculiarly irritating substance. At one time it was thought (e.g., by Dr. DAY of Stafford) that ozone was this substance, but this notion has not been maintained, having but little to support it. Dr. BAKER now advances an even simpler explanation, which involves a relation to the absolute (not the relative) humidity of the air. He points out that since in dry and cold seasons there is a greater exhalation of watery vapour, there must be a tendency under such conditions to the accumulation of non-volatile salts, as chloride of sodium, in the air passages of the lungs. Five-and-thirty years ago Dr. BEALE showed that the pneumonic lung contained an excess of chloride of sodium, and it has generally been thought that this explained the disappearance of that salt from the urine during the progress of hepatisation. But Dr. BAKER does not regard the matter solely from this point of view, and suggests that the presence of this excess of salt operates in exciting exosmosis of serum from the bloodvessels into the air-cells. Clearly, however, this theory is by itself insufficient, as it leaves just as much unexplained as ever the preference of one lobe or lung over another as the seat of hepatisation. As a theory, it has the merit of advancing us one step beyond the mere "chill" doctrine, and is capable of extension to the etiology of bronchitis and broncho-pneumonia as well as of croupous pneumonia. Dr. BAKER, indeed, asks whether the reason of the greater prevalence of pneumonia in warm climates than in cold may not be due to the greater consumption of salt in the former than in the latter, where this article is not needed for the preservation of food. Nevertheless, we find it difficult to admit such a view as a final explanation, which involves, it will be seen, a relegation of the pneumonococcus to the position of an epiphyte; but at the same time every suggestion that aids in the simplification of ideas upon etiology should be welcomed; and the painstaking labour of Dr. BAKER in compiling statistics of pneumonia in relation to meteorological conditions deserves the fullest recognition.

Annotations.

"Ne quid nimis."

ARMY MEDICAL STAFF.

A SOCIETY JOURNAL has just made a savage onslaught on the army medical officers, because, forsooth, in the opinion of the writer of the article, the medical administration is "not only wasteful, but grossly inefficient." This Rip van Winkle appears suddenly to have awakened from a sleep of a quarter of a century's duration, for he believes the whole duty of the army doctors to be to "physic soldiers in the time of peace, and dress their wounds in time of war." He does not appear to have the most remote idea that such a thing as sanitary science exists, and has been cultivated in the army with a success which certainly entitles the officers of the department to great credit. His description of the life of our army medical officer as one "of ease, comfort, and idleness" is very far from the truth. We believe there is no branch of the service which works harder, or has a larger proportion of service in unhealthy climates, than the medical. His description of the medical "officer in a particularly gaudy uniform strutting down the high street of his garrison town" may have been true in the period before the commencement of his long sleep, but it is certainly not applicable to the present day; nor is his remark about the Army Medical Department breaking down in war at all nearer the truth, as was clearly shown at the inquiry presided over by Lord Morley in 1883. The suggestion made by the writer of the article to put the army doctor "on the same footing as the army chaplain, who does his work very well, and very cheaply too," would, if carried out, be most disastrous to the soldiers, for if cheapness is to be the important factor there can be no doubt that the medical staff would then be filled, if filled at all, only by those who were failures in civil life. Cheap they might be as regards money, but extravagantly dear as measured by the lives and health of the soldiers. We have quite as little sympathy as the writer of the article for those medical officers who "are for ever complaining about their 'position' and rank as compared with that of military officers"; but we differ from him in this, that while he would make the remark applicable to the whole department, we believe it to be so only to a small minority. The whole tone of the article gives rise to a strong impression that it has been inspired by those who raised such an unjustifiable outcry at the time of the Egyptian expedition, and who can hardly be expected to forget the signal defeat they experienced in the inquiry then instituted into the working of the departments. It also savours of the hostile feeling towards the medical officers which has on all convenient opportunities been manifested by a certain coterie at the Horse Guards, and which, we had trusted, might be considered among the errors of the past.

THE BLOOD IN DIABETES.

PROFESSOR LÉPINE has lately recorded in the *Revue de Médecine* a case of diabetes which terminated fatally in coma, and in which, for the first time, it was positively shown that in this state the blood loses its alkaline reaction. As far back as 1883, at the debate on diabetes at the Pathological Society, Dr. Ralfe first drew attention to the fact that the symptoms of diabetic coma were not unlike those produced in animals poisoned by an injection of acids into their veins, or whenever attempts were made to diminish the alkalinity of the blood by other means; whence the speaker inferred that the poison concerned was of an *acid* nature, which by decomposition in the urine became converted into acetone. This idea of "acid intoxication" has since

Digitized by Google

been generally adopted, and Minskowski has discovered the presence of an acid (oxybutyric) in diabetic urines which is capable of breaking up in aceto-acetic acid, and thus furnishing acetone. This acid does not, perhaps, exist in the blood and tissues in a free state, but is probably combined with some base with which it forms an acid salt. In Professor Lépine's case, intravenous injection of a saline fluid containing about an ounce each of sodium chloride and sodium bicarbonate to three pints of water was employed when the coma first set in. After this there was some immediate improvement from the coma, the pulse rallied, the temperature rose from 96° to 97·5° F., and the patient could speak, but not swallow. Twelve hours afterwards venesection was employed prior to the trial of a fresh injection, when it was found, in spite of the previous injection of a large quantity of alkali, the reaction of the blood was neutral—a clear proof, Professor Lépine thinks, of the acid nature of the disease, and its power to destroy the normal alkalinity of the blood. It may be a question, however, whether the injection of an alkaline bicarbonate into the blood in diabetic coma is a right procedure, for though the reaction of the salt is alkaline, yet its constitution is acid, and, as Dr. Ralfe pointed out some years ago, probably acts as an acid salt in its decomposition with other salts in the body, and so actually tends, after the immediate effect of its alkalinity has passed off, to diminish the alkalinity of the blood. Should this on further inquiry prove correct, it might be advisable to employ neutral sodium phosphate instead of the acid sodium carbonate for intravenous injections.

SCHOOL FEES DURING SICKNESS.

THE case of appeal heard in the Queen's Bench Division against the decision of a County Court judge, who had awarded a schoolmaster compensation for the removal of pupils by a parent on the occurrence of two mild cases of scarlet fever in the school, is of considerable interest to all parents. The congregation of large numbers of children in either private or public schools renders the occurrence of the acute infectious diseases of childhood almost inevitable from time to time, however thorough the precautions of the master may be. It would be unreasonable to expect the schoolmaster to bear the whole loss of such occurrences, especially if evidence is forthcoming that he has exercised all reasonable precautions to guard against the introduction of infectious illness among his pupils. But he might fairly be expected to share with the parent some of the loss that ensues from the removal of a pupil during convalescence, or the withdrawal of non-infected pupils on a threatened outbreak. A parent has of course a perfect right to remove a pupil, and the master has an equal right to stipulate the terms on which he is willing to accept pupils. To lessen the occasional friction between schoolmasters and parents a definite understanding should be arrived at at the commencement of the pupil's career. All parents should stipulate that on the occurrence of any outbreak of infectious illness they should be candidly informed of the nature and extent of the outbreak, nor should they be kept in ignorance of an isolated case. If the withdrawal of uninfected pupils is not considered necessary by the public medical officer of health in whose district the school is located, and the parent nevertheless decides to withdraw a pupil, the schoolmaster could scarcely be expected to incur loss thereby; but if, on the other hand, it is considered desirable, either from the extent or nature of the outbreak, to disperse the pupils, the master may fairly be expected to remit a portion of the school fees. His loss under these circumstances would be considerable, and so would the parents'; for the latter must make provision of a more or less costly nature for the care of a child during the period of the possible incubation of the disease to which the outbreak at school has exposed him. Some definite rule should be established at our public schools on these points, which would be a guide to private schoolmasters. A remission of one-third or half the school fees, according to circumstances, might reasonably be expected whenever the withdrawal of a pupil is considered desirable by the public medical officer of health.

TREATMENT OF HEPATIC COLIC.

OLIVE oil in large quantity is vaunted as a certain cure for hepatic colic due to gall-stones. Dr. Just Touatre of New Orleans has written an interesting account of self-cure of biliary colic and gall-stones, in the second number of a bi-monthly Roumanian journal (*Archives Roumanies de Médecine et de Chirurgie*), whose editor is M. Georges Assaky. The method of procedure was as follows: At seven in the evening a blue pill of the weight of 15 centigrammes was taken, and this was followed twelve hours later by the taking in one draught of twelve tablespoonfuls of olive oil; a quarter of an hour later a similar dose of olive oil was taken, and then the patient addressed himself to sleep on his right side. At nine o'clock the blue pill acted, producing a copious biliary evacuation, but no gall-stones. Three o'clock in the afternoon saw another bilious stool without stones, but from seven in the evening till midnight six stools were passed; the first two contained seventeen calculi of the size of a large pea of conical shape, greyish-yellow aspect, and soft consistence. Altogether sixty stones were evacuated, and six of these had the volume of an olive, and were of a black colour. The passage of these calculi by the cystic and biliary canals was for the most part unattended with pain, a few spasms being felt probably at the time of the movement of the large calculi. An inexpressible relief was obtained from the pains over the liver and shoulder, which had previously caused much distress; the liver also diminished in size. For three months Dr. Touatre enjoyed perfect health, when the trouble commenced again; the olive oil was repeated in similar fashion, and with the result that eighteen more calculi were discharged by the bowel. Since then he has enjoyed excellent health. He admits that some courage is required to swallow the large doses of olive oil.

FEVER IN LONDON.

IN our last issue we noted the temporary increase of scarlet fever during the week ending November 25th, and pointed out that this increase corresponded with the experience of past years. The number of cases admitted that week into the hospitals of the Metropolitan Asylums Board was 191, and during the subsequent week ending Dec. 2nd the fresh admissions numbered 173, showing the return to a general decline. This decline should be more marked during December, so that by the middle of January the number of fresh attacks should not be in excess of the average during the year. The published returns of the last few days show that this result is likely to be attained. The vacant beds on Dec. 7th were 204 in number, in addition to which there were twenty-five beds reserved for special isolation. The opinion we expressed as to the absence of necessity for the newly ordered hospital accommodation was therefore well founded. During last week fifteen cases of enteric fever were admitted into the hospitals, as against twenty-six in the preceding week. Small-pox contributed three cases, one from the Wandsworth and two from the Poplar districts. At the meeting of the Asylums Board which was held last Saturday, Deputy Inspector-General Bostock called attention to the fact that a gentleman living in Paddington had applied at the Fulham Hospital for the admission of his two sons, who were suffering from fever, and on being informed that the hospital had no wards for paying patients, he obtained an

Digitized by Google

ambulance from the ambulance station, and thus procured their removal. The circumstance is important as affording further illustration that the hospitals are regarded as the means of isolation not only of poor persons, but of cases of fever occurring in all classes of society. A report of the General Purposes Committee was brought forward by Mr. Scovell, dealing with the reply of the Local Government Board to the Managers' application for authority to remove to their hospitals all persons suffering from fever or small-pox, whose removal should be sought by duly qualified medical practitioners. It will be recollected that the Local Government Board were of opinion that they had no authority to issue such an order, but they pointed out that under certain circumstances the Managers were authorised to receive persons who presented themselves at the hospital gates. The Managers at their last meeting, determined to explain to the Local Government Board that the difficulty under which they suffered was with regard to the admission of cases in the Managers' ambulances, and that 40 per cent. of the patients recently admitted had been received without an order from a relieving officer or master of a workhouse. They therefore desired to impress upon the Board the absolute necessity of taking steps without further delay to obtain from Parliament such powers as would directly authorise the Managers to remove to their hospitals all persons suffering from fever or small-pox, whose removal should be applied for by duly qualified medical practitioners.

THE ELECTRICAL PHENOMENA OF THE SALIVARY GLANDS.

THE electrical phenomena accompanying the excitation of so-called secretory and trophic nerve fibres in the salivary glands of the dog and cat have been studied by Mr. Rose Bradford in the Physiological Laboratory of University College, London. This observer, with Mr. Bayliss, had previously found that in the dog excitation of the chorda tympani caused a large variation, indicating the surface of the gland to become negative to the hilus; and excitation of the sympathetic caused the outer surface to become positive to the hilus, this variation being neither so rapid nor so great as is effected by excitation of the chorda. In the cat excitation of the chorda or of the sympathetic caused a diaphasic variation. Finally, in the parotid of the dog excitation of the tympanic plexus caused the surface of the gland to become negative to the hilus, and excitation of the sympathetic caused the surface to become positive to the hilus. It seemed desirable, as these results were very constant and definite, to continue the work and try to determine, if possible, which of the many changes that occur during the activity of these glands are concerned in the production of the electrical phenomena. In the communication published in the Collected Papers (No. 6) from the Physiological Laboratory of University College, London, Mr. Bradford brings forward evidence to show that the electrical variation of these salivary glands is not directly connected with the vaso-motor changes resulting from excitation. It is concluded that a flow of secretion is intimately connected with a certain definite electrical variation. The first phase is probably due to one or more of the following three causes: (1) the actual movement of the fluid through the cells and ducts; (2) the change in the gland cells which presumably precedes the passage of blood through them; (3) the anabolic changes that are supposed by some observers to follow the excitation of secretory fibres. Mr. Bradford concludes that there is not sufficient evidence to show that the first phase is due to anabolic changes; whereas there is a very considerable mass of facts to show that it is connected with the flow of liquid. The difficulty of estimating the latent period of the actual secretion makes it uncertain whether the variation accompanies or precedes the flow. Evidence is adduced tending to show that the passage of the fluid through the ducts is not the cause of the electrical effects. Hence the first phase is due probably either to the passage of the fluid part of the secretion through the walls of the alveoli, or to the changes in the gland structures that follow the excitation of a secretory nerve and precede the actual flow. The second phase is most likely to be ascribed to the changes in the gland cells leading to the elaboration of the organic constituents of the saliva.

THE CAUSE AND PREVENTION OF FOG.
